Azov Wiper

According to Checkpoint, this malware is a wiper instead of ransomware as self-announced. It is manually written in FASM, unrecoverably overwriting data in blocks of 666 bytes, using multi-threading.

The tag is: *misp-galaxy:malpedia="Azov Wiper"*

Azov Wiper is also known as:

Babadeda

According to PCrisk, Babadeda is a new sample in the crypters family, allowing threat actors to encrypt and obfuscate the malicious samples. The obfuscation allows malware to bypass the majority of antivirus protections without triggering any alerts. According to the researchers' analysis, Babadeda leverages a sophisticated and complex obfuscation that shows a very low detection rate by anti-virus engines.

The tag is: *misp-galaxy:malpedia="Babadeda"*

Babuk (Windows)

Babuk Ransomware is a sophisticated ransomware compiled for several platforms. Windows and ARM for Linux are the most used compiled versions, but ESX and a 32bit old PE executable were observed over time. as well It uses an Elliptic Curve Algorithm (Montgomery Algorithm) to build the encryption keys.

The tag is: *misp-galaxy:malpedia="Babuk (Windows)"*

Babuk (Windows) is also known as:

- Babyk
- Vasa Locker

BabyShark

BabyShark is Microsoft Visual Basic (VB) script-based malware family first seen in November 2018. The malware is launched by executing the first stage HTA from a remote location, thus it can be delivered via different file types including PE files as well as malicious documents. It exfiltrates system information to C2 server, maintains persistence on the system, and waits for further instruction from the operator

BACKBEND

FireEye describes BACKBEND as a secondary downloader used as a backup mechanism in the case the primary backdoor is removed. When executed, BACKBEND checks for the presence of the mutexes MicrosoftZj or MicrosoftZjBak (both associated with BACKSPACE variants). If either of the mutexes exist, the malware exits.

BADAUDIO

According to Google, BADAUDIO is a custom first-stage downloader written in C++ that downloads, decrypts, and executes an AES-encrypted payload from a hard-coded command and control (C2) server. The malware collects basic system information, encrypts it using a hard-coded AES key, and sends it as a cookie value with the GET request to fetch the payload. The payload, in one case identified as Cobalt Strike Beacon, is decrypted with the same key and executed in memory.

BalkanDoor

According to ESET, BalkanDoor is a simple backdoor with a small number of commands (download and execute a file, create a remote shell, take a screenshot). It can be used to automate tasks on the compromised computer or to automatically control several affected computers at once. We have seen six versions of the backdoor, with a range of supported commands, evolve since 2016.

BalkanRAT

The goal of BalkanRAT which is a more complex part of the malicious Balkan-toolset (cf. BalkanDoor) is to deploy and leverage legitimate commercial software for remote administration. The malware has several additional components to help load, install and conceal the existence of the remote desktop software. A single long-term campaign involving BalkanRAT has been active at least from January 2016 and targeted accouting departments of organizations in Croatia, Serbia, Montenegro, and Bosnia and Herzegovina (considered that the contents of the emails, included links and decoy PDFs all were involving taxes). It was legitimaly signed and installed by an exploit of the WinRAR ACE vulnerability (CVE-2018-20250).

Bandook

Bandook malware is a remote access trojan (RAT) first seen in 2007 and has been active for several years. Written in both Delphi and C++, it was first seen as a commercial RAT developed by a Lebanese creator named PrinceAli. Over the years, several variants of Bandook were leaked online, and the malware became available for public download.

BanPolMex RAT

BanPolMex is a remote access trojan that uses TCP for communication.

It uses an RC4-like stream cipher called Spritz for encryption of its configuration and network traffic.

It sends detailed information about the victim's environment, like computer name, Windows version, free space of memory and all drives, processor identifier and architecture, system locale,

system metrics, manufacturer, and network configuration.

It supports almost 30 commands that include operations on the victim's filesystem, basic process management, file exfiltration, and the download and execution of additional tools from the attacker's C&C server. As in many RATs from Lazarus arsenal, the commands are indexed by 32-bit integers. However, in this case the indicis are convertible into a meaningful ASCII representation, that even suggests the functionality: SLEP, HIBN, DRIV, DIR, DIRP, CHDR, RUN, RUNX, DEL, WIPE, MOVE, FTIM, NEWF, DOWN, ZDWN, UPLD, PVEW, PKIL, CMDL, DIE, GCFG, SCFG, TCON, PEEX, PEIN.

It has aclui.dll as the internal DLL name. It contains statically linked code from open-source libraries like libcurl (version 7.47.1) or zLib (version 0.15).

BanPolMex RAT was delivered for victims of a watering hole campaign targeting employees of Polish and Mexican banks, that was discovered in February 2017. It is usually loaded by HOTWAX.

BaoLoader

According to Expel, the developers behind the recent AppSuite-PDF and PDF Editor campaigns have used at least 26 code-signing certificates over the last seven years to make their software appear legitimate. Due to different use of and certificate clustering, the malware is believed different from both Chromeloader and TamperedChef.

BATLOADER

According to PCrisk, BATLOADER is part of the infection chain where it is used to perform the initial compromise. This malware is used to execute payloads like Ursnif. Our team has discovered BATLOADER after executing installers for legitimate software (such as Zoom, TeamViewer Visual Studio) bundled with this malware. We have found those installers on compromised websites.

The tag is: *misp-galaxy:malpedia="BATLOADER"*

BATLOADER is also known as:

BazarBackdoor

BazarBackdoor is a small backdoor, probably by a TrickBot "spin-off" like anchor. Its called team9 backdoor (and the corresponding loader: team9 restart loader).

For now, it exclusively uses Emercoin domains (.bazar), thus the naming. FireEye uses KEGTAP as name for BazarLoader and BEERBOT for BazarBackdoor.

The tag is: *misp-galaxy:malpedia="BazarBackdoor"*

BazarBackdoor is also known as:

- BEERBOT
- KEGTAP
- Team9Backdoor
- bazaloader
- bazarloader

BEATDROP

According to Mandiant, BEATDROP is a downloader written in C that uses Atlassian's project management service Trello for C&C. BEATDROP uses Trello to store victim information and retrieve AES-encrypted shellcode payloads to be executed. BEATDROP then injects and executes downloaded payloads into a suspended process. Upon execution, BEATDROP maps a copy of ntdll.dll into memory to execute shellcode in its own process. The sample then creates a suspended thread with RtlCreateUserThread the thread points to NtCreateFile. The sample changes execution to shellcode and resumes the thread. The shellcode payload is retrieved from Trello and is targeted per victim. Once the payload has been retrieved, it is deleted from Trello.

The tag is: *misp-galaxy:malpedia="BEATDROP"*

BEATDROP is also known as:

Belonard

Once set up in the system, Trojan.Belonard replaces the list of available game servers in the game client and creates proxies on the infected computer to spread the Trojan. As a rule, proxy servers show a lower ping, so other players will see them at the top of the list. By selecting one of them, a player gets redirected to a malicious server where their computer become infected with Trojan.Belonard.

BianLian (Windows)

BianLian is a GoLang-based ransomware that continues to breach several industries and demand large ransom amounts. The threat actors also use the double extortion method by stealing an affected organization’s files and leaking them online if the ransom is not paid on time. BianLian

gains access to victim systems through valid Remote Desktop Protocol (RDP) credentials, uses open-source tools and command-line scripting for discovery and credential harvesting, and exfiltrates victim data via File Transfer Protocol (FTP), Rclone, or Mega. BianLian originally employed a double-extortion model in which they encrypted victims' systems after exfiltrating the data; however, around January 2023, they shifted to primarily exfiltration-based extortion. The BianLian ransomware uses goroutines and encrypts files in chunks to quickly hijack an infected system. The ransomware adds its own extension to each encrypted file.

The tag is: *misp-galaxy:malpedia="BianLian (Windows)"*

BitRAT

According to Bitdefender, BitRAT is a notorious remote access trojan (RAT) marketed on underground cybercriminal web markets and forums. Its price tag of $20 for lifetime access makes it irresistible to cybercriminals and helps the malicious payload spread.

Furthermore, each buyer's modus operandi makes BitRAT even harder to stop, considering it can be employed in various operations, such as trojanized software, phishing and watering hole attacks.

BitRAT's popularity arises from its versatility. The malicious tool can perform a wide range of operations, including data exfiltration, UAC bypass, DDoS attacks, clipboard monitoring, gaining unauthorized webcam access, credential theft, audio recording, XMRig coin mining and generic keylogging.

Black Basta (Windows)

"Black Basta" is a new ransomware strain discovered during April 2022 - looks in dev since at least early February 2022 - and due to their ability to quickly amass new victims and the style of their

negotiations, this is likely not a new operation but rather a rebrand of a previous top-tier ransomware gang that brought along their affiliates.

BlackCat (Windows)

ALPHV, also known as BlackCat or Noberus, is a ransomware family that is deployed as part of Ransomware as a Service (RaaS) operations. ALPHV is written in the Rust programming language and supports execution on Windows, Linux-based operating systems (Debian, Ubuntu, ReadyNAS, Synology), and VMWare ESXi. ALPHV is marketed as ALPHV on cybercrime forums, but is commonly called BlackCat by security researchers due to an icon of a black cat appearing on its leak site. ALPHV has been observed being deployed in ransomware attacks since November 18, 2021.

ALPHV can be configured to encrypt files using either the AES or ChaCha20 algorithms. In order to maximize the amount of ransomed data, ALPHV can delete volume shadow copies, stop processes and services, and stop virtual machines on ESXi servers. ALPHV can self-propagate by using PsExec to remote execute itself on other hosts on the local network.

BlackEnergy

BlackEnergy, its first version shortened as BE1, started as a crimeware being sold in the Russian cyber underground as early as 2007. Initially, it was designed as a toolkit for creating botnets for conducting DDoS attacks. It supported a variety of flooding commands including protocols like ICMP, TCP SYN, UDP, HTTP and DNS. Among the high profile targets of cyber attacks utilising BE1 were a Norwegian bank and government websites in Georgia three weeks before Russo-Georgian War.

Version 2 of BlackEnergy, BE2, came in 2008 with a complete code rewrite that introduced a protective layer, a kernel-mode rootkit and a modular architecture. Plugins included mostly DDoS attacks, a spam plugin and two banking authentication plugins to steal from Russian nad Ukrainian banks. The banking plugin was paired with a module designed to destroy the filesystem. Moreover, BE2 was able to - download and execute a remote file; - execute a local file on the infected computer; - update the bot and its plugins;

The Industrial Control Systems Cyber Emergency Response Team issued an alert warning that BE2 was leveraging the human-machine interfaces of industrial control systems like GE CIMPLICITY, Advantech/Broadwin WebAccess, and Siemens WinCC to gain access to critical infrastructure networks.

In 2014, the BlackEnergy toolkit, BE3, switched to a lighter footprint with no kernel-mode driver component. Its plugins included: - operations with victim's filesystem - spreading with a parasitic infector - spying features like keylogging, screenshoots or a robust password stealer - Team viewer and a simple pseudo "remote desktop" - listing Windows accounts and scanning network -

destroying the system

Typical for distribution of BE3 was heavy use of spear-phishing emails containing Microsoft Word or Excel documents with a malicious VBA macro, Rich Text Format (RTF) documents embedding exploits or a PowerPoint presentation with zero-day exploit CVE-2014-4114.

On 23 December 2015, attackers behind the BlackEnergy malware successfully caused power outages for several hours in different regions of Ukraine. This cyber sabotage against three energy companies has been confirmed by the Ukrainian government. The power grid compromise has become known as the first-of-its-kind cyber warfare attack affecting civilians.

BlackMatter (Windows)

According to PCrisk, BlackMatter is a piece of malicious software categorized as ransomware. It operates by encrypting data for the purpose of making ransom demands for the decryption tools. In other words, files affected by BlackMatter are rendered inaccessible, and victims are asked to pay - to recover access to their data.

During the encryption process, files are appended with an extension consisting of a random character string. For example, a file initially named "1.jpg" would appear as something similar to "1.jpg.k5RO9fVOl". After this process is complete, the ransomware changes the desktop wallpaper and created a ransom note - "[random_string].README.txt" (e.g., k5RO9fVOl.README.txt).

BLINDINGCAN

BLINDINGCAN is a remote access trojan that communicates with its C&C server via HTTP(S). It uses a (custom) RC4 or AES for encryption and decryption of its configuration and network traffic. It sends information about the victim's environment, like computer name, IP, Windows product name and processor name. It supports around 30 commands that include operations on the victim's filesystem, basic process management, command line execution, file exfiltration, configuration

update, and the download and execution of additional payloads from the attackers' C&C. The commands are indexed by 16-bit integers, starting with the index 0x2009 and going incrementally up to 0x2057, with some indicis being skipped. It uses various parameter names in its HTTP POST requests, mostly associated with web servers running bulletin board systems, like bbs, article, boardid, s_board, page, idx_num, etc. It contains specific RTTI symbols like ".?AVCHTTP_Protocol@@", ".?AVCFileRW@@" or ".?AVCSinSocket@@". BLINDINGCAN RAT is a flagship payload deployed in many Lazarus attacks, especially in the Operation DreamJob campaigns happening in 2020-2022.

The tag is: *misp-galaxy:malpedia="BLINDINGCAN"*

BLINDINGCAN is also known as:

- AIRDRY
- ZetaNile

BookCodes RAT

BookCodesRAT is a remote access trojan that uses HTTP(S) for communication. It supports around 25 commands that include operations on the victim's filesystem, basic process management and the download and execution of additional tools from the attacker's arsenal. They are indexed by 32-bit integers, starting with the value 0x97853646.

BookCodesRAT uses mostly compromised South Korean web servers for the C&C traffic and is usually deployed against South Korean targets.

The tag is: *misp-galaxy:malpedia="BookCodes RAT"*

BookCodes RAT is also known as:

- BookCodesTea

BOOSTWRITE

FireEye describes BOOSTWRITE as a loader crafted to be launched via abuse of the DLL search order of applications which load the legitimate ‘Dwrite.dll’ provided by the Microsoft DirectX Typography Services. The application loads the ‘gdi’ library, which loads the ‘gdiplus’ library, which ultimately loads ‘Dwrite’. Mandiant identified instances where BOOSTWRITE was placed on the file system alongside the RDFClient binary to force the application to import DWriteCreateFactory from it rather than the legitimate DWrite.dll.

Broomstick

Oyster is a backdoor malware written in C++ that first appeared in July 2023. It allows for remote sessions, supporting tasks such as file transfer and command-line processing. This malware has been used by numerous threat actors as a tool to facilitate ransomware intrusions. The distribution of Oyster has likely occurred through various methods, as suggested by the build identifiers found in examined samples. Additionally, Oyster is capable of collecting basic system data and communicates with a command-and-control (C2) server. It can execute commands via cmd.exe and run additional files.

In August 2024, a new version of Oyster was discovered that featured a new command-and-control (C2) communication protocol format. This 2024 version contained plaintext strings and lacked code obfuscation, suggesting it was still in development. In contrast to the 2024 version, the new 2025 Oyster version does not send C2 messages in plaintext, instead reintroducing the substitution cipher that was present in earlier versions of Oyster.

Brute Ratel C4

Brute Ratel C4 (BRC4) is a commercial framework for red-teaming and adversarial attack simulation, which made its first appearance in December 2020. It was specifically designed to evade detection by endpoint detection and response (EDR) and antivirus (AV) capabilities. BRC4 allows operators to deploy a backdoor agent known as Badger (aka BOLDBADGER) within a target environment. This agent enables arbitrary command execution, facilitating lateral movement, privilege escalation, and the establishment of additional persistence avenues. The Badger backdoor agent can communicate with a remote server via DNS over HTTPS, HTTP, HTTPS, SMB, and TCP, using custom encrypted channels. It supports a variety of backdoor commands including shell command execution, file transfers, file execution, and credential harvesting. Additionally, the Badger agent can perform tasks such as port scanning, screenshot capturing, and keystroke logging. Notably, in September 2022, a cracked version of Brute Ratel C4 was leaked in the cybercriminal underground, leading to its use by threat actors.

BTCWare

According to PCRisk, BTCWare is an updated version of a ransomware-type virus called Crptxxx. This ransomware is distributed via a malicious application called "Rogers Hi-Speed Internet". Once infiltrated, BTCWare encrypts files and appends filenames with the ".btcware" extension. Newer variants of this ransomware append .shadow, .payday, .wyvern, .nuclear, .aleta, .gryphon, .nopasaran, .blocking, .xfile, .master, .onyon, .theva, .cryptobyte or .cryptowin extensions to encrypted files. BTCWare then creates an HTM file ("*HOW_TO_FIX*!.hta.htm"), placing it on the desktop. Other variants of this ransomware use !*RESTORE_FILES*#!.inf file to store their ransom demanding message.

BundleBot

Bundlebot is an info stealer that abuses the single-file dotnet bundle which operates as a self-contained executable that does not require any preinstalled dotnet runtime version. Bundlebot functionality targets a wide variety of data including the victim's system information, browser data, telegram data, discord token, Facebook account information, and screenshots.

CaddyWiper

CaddyWiper is another destructive malware believed to be deployed to target Ukraine.

CaddyWiper wipes all files under C:\Users and all also all files under available drives from D: to Z: by overwriting the data with NULL value. If the target file is greater than 0xA00000 bytes in size (10MB), it will only wipe the first 0xA00000 bytes.

It also wipes disk partitions from \\.\PHYSICALDRIVE9 to \\.\PHYSICALDRIVE0 by overwriting the first 0x780 bytes with NULL.

The tag is: *misp-galaxy:malpedia="CaddyWiper"*

CaddyWiper is also known as:

- KillDisk.NCX

Carbanak

MyCERT states that Carbanak is a remote backdoor designed for espionage, data exfiltration, and to remote control.

The attacker deploy malware via spear phishing email to lure the user to open and run the malicious attachment that will infect the machine. The main objective of this campaign is primarily to remotely control the infected machine and gain control of the internal destinations of money processing services such as Automated Teller Machines(ATM) and financial accounts. The following information are the malware capabilities:

Cardinal RAT

Cardinal RAT is a remote access Trojan capable of stealing username and credentials, cleaning out cookies from browsers, keylogging and capturing screenshots on targeted systems. It is delivered via a downloader dubbed “Carp” which uses malicious macros in Microsoft Excel documents to compile embedded source code into an executable, which then deploys the Cardinal RAT malware family.

The tag is: *misp-galaxy:malpedia="Cardinal RAT"*

CargoBay

CargoBay is a newer malware family which was first observed in 2022 and is notable for being written in the Rust language. CargoBay is likely based on source code taken from 'Black Hat Rust' GitHub project (https://github.com/skerkour/black-hat-rust). CargoBay is usually distributed via phishing emails, and the malware binaries may be disguised as legitimate applications. Upon execution, the malware starts by performing environmental checks such as checking its execution path and the configured system language. If the tests pass, then the malware proceeds to gather basic system information and register with its C2 via HTTP from which it receives JSON-formatted jobs to carry out. CargoBay can execute commands via the command line and downloading additional malware binaries.

The tag is: *misp-galaxy:malpedia="CargoBay"*

CargoBay is also known as:

Casper

ESET describes Casper as a well-developed reconnaissance tool, making extensive efforts to remain unseen on targeted machines. Of particular note are the specific strategies adopted against anti-malware software. Casper was used against Syrian targets in April 2014, which makes it the most recent malware from this group publicly known at this time.

Chaperone

According to Kaspersky GReAT and AMR, TajMahal is a previously unknown and technically sophisticated APT framework discovered by Kaspersky Lab in the autumn of 2018. This full-blown spying framework consists of two packages named Tokyo and Yokohama. It includes backdoors, loaders, orchestrators, C2 communicators, audio recorders, keyloggers, screen and webcam grabbers, documents and cryptography key stealers, and even its own file indexer for the victim's

machine. We discovered up to 80 malicious modules stored in its encrypted Virtual File System, one of the highest numbers of plugins they have ever seen for an APT toolset.

CHEESETRAY

CHEESETRAY is a sophisticated proxy-aware backdoor that can operate in both active and passive mode depending on the passed command-line parameters. The backdoor is capable of enumerating files and processes, enumerating drivers, enumerating remote desktop sessions, uploading and downloading files, creating and terminating processes, deleting files, creating a reverse shell, acting as a proxy server, and hijacking processes among its other functionality. The backdoor communicates with its C&C server using a custom binary protocol over TCP with port specified as a command-line parameter.

Chisel (Windows)

Chisel is an open-source project by Jaime Pillora (jpillora) that allows tunneling TCP and UDP connections via HTTP. It is available across platforms and written in Go. While benign in itself, Chisel has been utilized by multiple threat actors. It was for example observed by SentinelOne during a PYSA ransomware campaign to achieve persistence and used as backdoor. Github: https://github.com/jpillora/chisel

Choziosi (Windows)

Choziosi is a browser hijacker for Chrome. It was first seen in January 2022. It commonly infects users via pirated media downloads like games, software, wallpapers or movies. The initial infectors are available for several platforms such as Mac and Windows.

Its main component is the Chrome browser extension written in JavaScript with the purpose of serving advertisments and hijacking search requests to Google, Yahoo and Bing.

The tag is: *misp-galaxy:malpedia="Choziosi (Windows)"*

Choziosi (Windows) is also known as:

ChrGetPdsi Stealer

ChrGetPdsi is a basic infostealer written in Golang which is designed to steal browser history and logins, and targets Chrome, Edge, and Firefox. The output is written to a text file named chrgetpdsi.txt. Based on the samples analysed, the malware does not appear to have networking capabilities, and therefore it is likely that it is intended to be used in a post-compromise situation where the attacker already has access to the target system and can retrieve the created output file via other means.ChrGetPdsi has been observed being deployed by the Broomstick malware.

ClipBanker

The ClipBanker Trojan is known as an information stealer and spy trojan, it aims to steal and record any type of sensitive information from the infected environment such as browser history, cookies, Outlook data, Skype, Telegram, or cryptocurrency wallet account addresses. The main goal of this threat is to steal confidential information. The ClipBanker uses PowerShell commands for executing malicious activities. The thing that made the ClipBanker unique is its ability to record various banking actions of the user and manipulate them for its own benefit. The distribution method of the ClipBanker is through phishing emails or through social media posts that lure users to download malicious content.

The tag is: *misp-galaxy:malpedia="ClipBanker"*

Clop (Windows)

Clop is a ransomware which uses the .clop extension after having encrypted the victim's files. Another unique characteristic belonging with Clop is in the string: "Dont Worry C|0P" included into the ransom notes. It is a variant of CryptoMix ransomware, but it additionally attempts to disable Windows Defender and to remove the Microsoft Security Essentials in order to avoid user space detection.

The tag is: *misp-galaxy:malpedia="Clop (Windows)"*

CLOUDBURST

CLOUDBURST aka NickelLoader is an HTTP(S) downloader.

It recognizes a set of four basic commands, all five letters long, like abcde, avdrq, gabnc and dcrqv (alternatively: eknag, eacec, hjmwk, wohnp). The most important functionality is to load a received buffer, either as a DLL via the MemoryModule implementation, or as a shellcode.

It uses AES for encryption and decryption of network traffic. It usually sends the following information back to its C&C server: computer name, product name and the list of running processes. Typically, it uses two hardcoded parameter names for its initial HTTP POST requests: gametype and type (alternatively: type and code).

The CLOUDBURST payload is disguised as mscoree.dll and is side-loaded via a legitimate Windows binary PresentationHost.exe with the argument -embeddingObject. It comes either as a trojanized plugin project for Notepad++ (usually FingerText by erinata), or as a standalone DLL loaded by a dropper, which is a trojanized plugin project as well (usually NppyPlugin by Jari Pennanen).

The CLOUDBURST malware was used in Operation DreamJob attacks against an aerospace company and a network running Microsoft Intune software in Q2-Q3 2022.

CloudEyE

CloudEyE (initially named GuLoader) is a small VB5/6 downloader. It typically downloads RATs/Stealers, such as Agent Tesla, Arkei/Vidar, Formbook, Lokibot, Netwire and Remcos, often but not always from Google Drive. The downloaded payload is xored.

The tag is: *misp-galaxy:malpedia="CloudEyE"*

CloudEyE is also known as:

- GuLoader
- vbdropper

CloudDuke

F-Secure describes CloudDuke as a malware toolset known to consist of, at least, a downloader, a loader and two backdoor variants. The CloudDuke downloader will download and execute additional malware from a preconfigured location. Interestingly, that location may be either a web address or a Microsoft OneDrive account. Both CloudDuke backdoor variants support simple backdoor functionality, similar to SeaDuke. While one variant will use a preconfigured C&C server over HTTP or HTTPS, the other variant will use a Microsoft OneDrive account to exchange commands and stolen data with its operators.

Cobalt Strike

Cobalt Strike is a paid penetration testing product that allows an attacker to deploy an agent named 'Beacon' on the victim machine. Beacon includes a wealth of functionality to the attacker, including, but not limited to command execution, key logging, file transfer, SOCKS proxying, privilege escalation, mimikatz, port scanning and lateral movement. Beacon is in-memory/file-less, in that it consists of stageless or multi-stage shellcode that once loaded by exploiting a vulnerability or executing a shellcode loader, will reflectively load itself into the memory of a process without touching the disk. It supports C2 and staging over HTTP, HTTPS, DNS, SMB named pipes as well as forward and reverse TCP; Beacons can be daisy-chained. Cobalt Strike comes with a toolkit for developing shellcode loaders, called Artifact Kit.

The Beacon implant has become popular amongst targeted attackers and criminal users as it is well written, stable, and highly customizable.

The tag is: *misp-galaxy:malpedia="Cobalt Strike"*

Cobalt Strike is also known as:

- Agentemis
- BEACON

CobInt

CobInt, is a self-developed backdoor of the Cobalt group. The modular tool has capabilities to collect

initial intelligence information about the compromised machine and stream video from its desktop. If the operator decides that the system is of interest, the backdoor will download and launch CobaltStrike framework stager. It's CRM mailslot module was also observed being downloaded by ISFB.

CoffeeLoader

Zscaler ThreatLabz states that this sophisticated malware family likely originated around September 2024. The purpose of the malware is to download and execute second-stage payloads while evading detection by endpoint-based security products. The malware uses numerous techniques to bypass security solutions, including a specialized packer called Armoury that utilizes the GPU, call stack spoofing, sleep obfuscation, and the use of Windows fibers. It also contains a backup DGA and is capable of deploying Rhadamanthys shellcode. ThreatLabz has observed CoffeeLoader being distributed via SmokeLoader, and both malware families share some behavioral similarities.

Coinminer

Coinminer is an unwanted malicious software which uses the victim's computational power (CPU and RAM mostly) to mine for coins (for example Monero or Zcash). The malware achieves persistence by adding one of the opensource miners on startup without the victim's consensus.

Most sophisticated coin miners use timer settings or cap the CPU usage in order to remain stealthy.

Cold$eal

Cold$eal is a packer for encrypting (sealing) malware. It contains some AV-evasion techniques as well as some sandbox-detection. It was developed by $@dok (aka Sadok aka Coldseal). It was available as a cryptor service under the url coldseal.us and was later sold as a toolkit consisting of the cryptor and a custom made cryptostub including a FuD garantee backed by free update to the cryptostub. The payload was encrypted using RC4 and added to the cryptostub as a resource. The encryption key itself was stored inside the resource as well. Upon start the cryptostub would extract the key, decrypt the payload and perform a selfinjection using the now decrypted payload. Note: The packed sample provided contains some harmless payload, while the unpacked sample is the bare cryptostub without a payload.

The tag is: *misp-galaxy:malpedia="Cold$eal"*

ColdStealer

ColdStealer is a relatively new malicious program that was discovered in 2022. Like many other stealers its main purpose is to steal credentials and information from web browsers, in addition to stealing cryptocurrency wallets, FTP credentials, various files and information about the system such as OS version, system language, processor type and clipboard data. When the infostealer collects information that will be stolen, it saves the information in the ZIP form instead of files in the memory. Doing so will allow the malware to bypass detection as there are no traces of files and execution. The only known method of delivering stolen information to cybercriminals is by sending a ZIP archive to the hardcoded command and control (C2) server.

The tag is: *misp-galaxy:malpedia="ColdStealer"*

Colibri Loader

According to cloudsek, Colibri Loader is a form of malware designed to facilitate the installation of additional malware types on an already compromised system. This loader employs various techniques to evade detection, such as excluding the Import Address Table (IAT) and utilizing encrypted strings to complicate analysis. Similar to other loader malware, Colibri can be utilized to deploy information-stealing malware, potentially leading to significant loss of sensitive data. As a result, users should exercise caution when encountering unfamiliar files on their systems.

ComeBacker

ComeBacker was found in a backdoored Visual Studio project that was used to target security researchers in Q4 2020 and early 2021.

It is an HTTP(S) downloader.

It uses the AES CBC cipher implemented through the OpenSSL's EVP interface for decryption of its configuration, and also for encryption and decryption of the client-server communication.

The parameter names in HTTP POST requests of the client are generated randomly. As the initial connection, the client exchanges the keys with the server via the Diffie–Hellman key agreement protocol for the elliptic curve secp521r1. The client generates a random 32-bytes long private key, and the server responds with its public key in a buffer starting with the wide character "0".

Next, the clients sends the current local time, and the server responds with a buffer containing multiple values separated with the pipe symbol. The typical values are the encrypted payload, the export to execute, and the MD5 hash of the decrypted DLL to verify the authenticity of the payload.

There are variants of ComeBacker without statically linked OpenSSL. In that case, the key exchange is omitted and AES CBC is replaced with HC-256.

Conti (Windows)

Conti is an extremely damaging ransomware due to the speed with which it encrypts data and spreads to other systems. It was first observed in 2020 and it is thought to be led by a Russia-based cybercrime group that goes under the Wizard Spider pseudonym. In early May 2022, the US government announced a reward of up to $10 million for information on the Conti ransomware gang.

Contopee

FireEye described this malware as a proxy-aware backdoor that communicates using a custom-encrypted binary protocol. It may use the registry to store optional configuration data. The backdoor has been observed to support 26 commands that include directory traversal, file system manipulation, data archival and transmission, and command execution.

CopperStealth

According to Trend Micro, CopperStealth's infection chain involves dropping and loading a rootkit, which later injects its payload into explorer.exe and another system process. These payloads are responsible for downloading and running additional tasks. The rootkit also blocks access to blocklisted registry keys and prevents certain executables and drivers from running. The task module is able to download and run additional payloads.

CopperStealer

According to PCRIsk, CopperStealer, also known as Mingloa, is a malicious program designed to steal sensitive/personal information. It also has the capability to cause chain infections (i.e., download/install additional malware).

Significant activity of CopperStealer has been observed in Brazil, India, Indonesia, Pakistan, and the Philippines. At the time of research, this malware had been noted being spread via websites offering illegal activation tools ("cracks") for licensed software products.

CountLoader

According to Silent Push, this malware exists in multiple versions, including .NET, PowerShell, and JScript. They believe it is part of an IAB toolset or used by a affiliate with ties to LockBit, BlackBasta, and Qilin ransomware groups. CountLoader was also recently used in a PDF-based phishing lure targeting individuals in Ukraine, in a campaign that impersonated the Ukrainian police.

The tag is: *misp-galaxy:malpedia="CountLoader"*

CountLoader is also known as:

https://www.fortinet.com/blog/threat-research/to-joke-or-not-to-joke-covid-22-brings-disaster-to-mbr

CoViper

PCRisk notes that CoViper is yet another Coronavirus/COVID-19-themed malware infection, most likely proliferated as a file related to the pandemic. It operates by rewriting the system Master Boot Record (MBR). It does not delete the original, but rather creates a backup and replaces it with a custom MBR.

Typically, malicious software that modifies MBRs do so to prevent the Operating System (OS) from being booted (i.e., started). It also displays a screen-encompassing message, often containing a ransom message - this disables user access to the device.

The tag is: *misp-galaxy:malpedia="CoViper"*

CoViper is also known as:

Table 3550. Table References

COZYDUKE

CozyDuke is not simply a malware toolset; rather, it is a modular malware platform formed around a core backdoor component. This component can be instructed by the C&C server to download and execute arbitrary modules, and it is these modules that provide CozyDuke with its vast array of functionality. Known CozyDuke modules include: • Command execution module for executing arbitrary Windows Command Prompt commands • Password stealer module • NT LAN Manager (NTLM) hash stealer module • System information gathering module • Screenshot module

The tag is: *misp-galaxy:malpedia="COZYDUKE"*

COZYDUKE is also known as:

- Cozer
- CozyBear
- CozyCar
- EuroAPT

CrackedCantil

According to ANY.RUN, this is a dropper for win.privateloader and its execution will lead to a cascade of downloads with a large variety of additional malware. The families include more loaders, information stealers, cryptominers, a proxy bot, and ultimately also ransomware. The execution order is orchestrated, e.g. as in data is stolen and exfiltrated before encryption. It is distributed through advertized cracked software, e.g. IDA Pro.

The tag is: *misp-galaxy:malpedia="CrackedCantil"*

CrackedCantil is also known as:

Crimson RAT

It was first discovered in 2017 and has since been used to attack organizations around the world. The malware is often distributed through phishing emails or by exploiting vulnerabilities in outdated security software. Once Crimson RAT is installed on a computer, it can be used to steal data, spy on users, and even take control of the infected computers.

Some of the features of Crimson RAT include:

Remote control of infected computers Data theft, such as passwords, files, and emails User spying Takeover of infected computers Locking of infected computers Extortion of payments

The tag is: *misp-galaxy:malpedia="Crimson RAT"*

Crimson RAT is also known as:

- SEEDOOR
- Scarimson

CrimsonIAS

According to ThreatConnect, CrimsonIAS is a Delphi-written backdoor dating back to at least 2017. It enables operators to run command line tools, exfiltrate files, and upload files to the infected machine. CrimsonIAS is notable as it listens for incoming connections only; making it different from typical Windows backdoors that beacons out.

The tag is: *misp-galaxy:malpedia="CrimsonIAS"*

CrimsonIAS is also known as:

CrypticConvo

CrypticConvo is a dropper trojan which appears to be embedded in an automatic generator framework to deliver the FakeM trojan. According to PaloaltoNetworks CrypticConvo and several additional trojans are believed to be included in a meta framework used by the "Scarlet Mimic" threat actor in order to quickly evade AV systems.

CryptoLocker

CryptoLocker is a new sophisticated malware that was launched in the late 2013. It is designed to attack Windows operating system by encrypting all the files from the system using a RSA-2048 public key. To decrypt the mentioned files, the user has to pay a ransom (usually 300 USD/EUR) or 2 BitCoins.

CyberGate

According to Subex Secure, CyberGate is a Remote Access Trojan (RAT) that allows an attacker to gain unauthorized access to the victim's system. Attackers can remotely connect to the compromised system from anywhere around the world. The Malware author generally uses this program to steal private information like passwords, files, etc. It might also be used to install malicious software on the compromised systems.

Cyclops

According to HarfangLabs, Cyclops is a malware platform written in Go which dates back to December 2023, and that they believe has been deployed against targets in the Middle-East in 2024. Cyclops allows operators to execute arbitrary commands on the target's file system, as well as pivot inside the infected network. Notably, Cyclops is controlled through a HTTP REST API which is exposed to operators within an SSH tunnel.

The tag is: *misp-galaxy:malpedia="Cyclops"*

Cyclops is also known as:

Cyrat

According to gdatasoftware, Cyrat ransomware uses Fernet to encrypt files. This is a symmetric encryption method meant for small data files that fit into RAM. While Fernet is not unusual itself, it is not common for ransomware and in this case even problematic.

The tag is: *misp-galaxy:malpedia="Cyrat"*

Dacls (Windows)

According to PCrisk, Dacls is the name of a remote access Trojan (RAT), a malicious program that allows cyber criminals to control infected computers remotely.

Research shows that this malware is tied to Lazarus Group (a group of cyber criminals) and targets Linux and the Windows Operating System. Typically, cyber criminals use RATs to steal sensitive, confidential information, infect systems with other malware, and so on. In any case, no RAT is harmless and should be uninstalled immediately.

The tag is: *misp-galaxy:malpedia="Dacls (Windows)"*

Dacls (Windows) is also known as:

DADJOKE

DADJOKE was discovered as being distributed via email, targeting a South-East Asian Ministry of Defense. It is delivered as an embedded EXE file in a Word document using remote templates and a unique macro using multiple GET requests. The payload is deployed using load-order hijacking with a benign Windows Defender executable. Stage 1 has only beacon+download functionality, made to look like a PNG file. Additional analysis by Kaspersky found 8 campaigns over 2019 and no activity prior to January 2019, DADJOKE is attributed with medium confidence to APT40.

DanaBot

Proofpoints describes DanaBot as the latest example of malware focused on persistence and stealing useful information that can later be monetized rather than demanding an immediate ransom from victims. The social engineering in the low-volume DanaBot campaigns we have observed so far has been well-crafted, again pointing to a renewed focus on “quality over quantity” in email-based threats. DanaBot’s modular nature enables it to download additional components, increasing the flexibility and robust stealing and remote monitoring capabilities of this banker.

The tag is: *misp-galaxy:malpedia="DanaBot"*

DanaBot is also known as:

- DanaTools

danbot

Danbot is a backdoor malware that is originally written in C#. Recent versions of Danbot are written in C++. Danbot is capable of giving a remote attacker remote access features such as running a cmd command, upload and download files, move and copy files. The backdoor commands are transmitted by either using HTTP or DNS protocols. The commands are encapsulated in an XML file that gets stored in disk. Danbot's backdoor component picks up the XML file where it decodes and decrypts the commands.

DarkComet

DarkComet is one of the most famous RATs, developed by Jean-Pierre Lesueur in 2008. After being used in the Syrian civil war in 2011, Lesuer decided to stop developing the trojan. Indeed, DarkComet is able to enable control over a compromised system through use of a simple graphic user interface. Experts think that this user friendliness is the key of its mass success.

The tag is: *misp-galaxy:malpedia="DarkComet"*

DarkComet is also known as:

Darksky

DarkSky is a botnet that is capable of downloading malware, conducting a number of network and application-layer distributed denial-of-service (DDoS) attacks, and detecting and evading security controls, such as sandboxes and virtual machines. It is advertised for sale on the dark web for $20. Much of the malware that DarkSky has available to download onto targeted systems is associated with cryptocurrency-mining activity. The DDoS attacks that DarkSky can perform include DNS amplification attacks, TCP (SYN) flood, UDP flood, and HTTP flood. The botnet can also perform a check to determine whether or not the DDoS attack succeeded and turn infected systems into a SOCKS/HTTP proxy to route traffic to a remote server.

DarkTequila

Dark Tequila is a complex malicious campaign targeting Mexican users, with the primary purpose of stealing financial information, as well as login credentials to popular websites that range from code versioning repositories to public file storage accounts and domain registrars.

The tag is: *misp-galaxy:malpedia="DarkTequila"*

DarkTortilla

DarkTortilla is a complex and highly configurable .NET-based crypter that has possibly been active since at least August 2015. It typically delivers popular information stealers and remote access trojans (RATs) such as AgentTesla, AsyncRat, NanoCore, and RedLine. While it appears to primarily deliver commodity malware, Secureworks® Counter Threat Unit™ (CTU) researchers identified DarkTortilla samples delivering targeted payloads such as Cobalt Strike and Metasploit. It can also deliver "addon packages" such as additional malicious payloads, benign decoy documents, and executables. It features robust anti-analysis and anti-tamper controls that can make detection, analysis, and eradication challenging.

From January 2021 through May 2022, an average of 93 unique DarkTortilla samples per week were uploaded to the VirusTotal analysis service. Code similarities suggest possible links between DarkTortilla and other malware: a crypter operated by the RATs Crew threat group, which was active between 2008 and 2012, and the Gameloader malware that emerged in 2021.

Darktrack RAT

According to PCrisk, DarkTrack is a malicious program classified as a Remote Access Trojan (RAT). This type of malware enables remote access and control over an infected device. The level of control these programs have varies, however, some can allow user-level manipulation of the affected machine.

The functionalities of RATs likewise varies and so does the scope of potential misuse. DarkTrack has a broad range of functions/capabilities, which make this Trojan a highly-dangerous piece of software.

The tag is: *misp-galaxy:malpedia="Darktrack RAT"*

DarkVision RAT

DarkVision_RAT is a highly customizable Remote Access Trojan (RAT) first identified in 2020. Written in C/C++ and assembler, it has gained popularity due to its low cost and broad range of functionalities, including keylogging, screenshot capture, file manipulation, process injection, remote code execution, and password theft. In July 2024, a malware campaign was observed distributing DarkVision_RAT using PureCrypter as a loader. This RAT communicates with its command and control server through a custom network protocol via sockets. It also employs evasion and privilege escalation techniques such as DLL hijacking, self-elevation, and process injection. DarkVision_RAT supports a wide array of commands and plugins, enabling additional capabilities like keylogging, remote access, password theft, audio recording, and screenshot capture.

DarkVNC

According to Enigmasoft, DarkVNC malware is a hacking tool that is available for purchase online. it is can be used as a Virtual Network Computing service, which means that the attackers can get full access to the targeted system via this malware. However, unlike a genuine Virtual Network Computing utility, the DarkVNC threat operates in the background silently. Therefore, it is highly likely that the victims may not notice that their systems have been compromised.

Defray

Defray is ransomware that appeared in 2017, and is targeted ransomware, mainly on the healthcare vertical.

The distribution of Defray has several notable characteristics: According to Proofpoint: " Defray is currently being spread via Microsoft Word document attachments in email The campaigns are as small as several messages each The lures are custom crafted to appeal to the intended set of potential victims The recipients are individuals or distribution lists, e.g., group@ and websupport@ Geographic targeting is in the UK and US Vertical targeting varies by campaign and is narrow and selective "

The tag is: *misp-galaxy:malpedia="Defray"*

Defray is also known as:

- Glushkov

DeimosC2

Trend Micro describes DeimosC2 as an open-source C&C framework that was released in June 2020. It is a fully-functional framework that allows for multiple attackers to access, create payloads for, and interact with victim computers. As a post-exploitation C&C framework, DeimosC2 will generate the payloads that need to be manually executed on computer servers that have been compromised through other means such as social engineering, exploitation, or brute-force attacks. Once it is deployed, the threat actors will gain the same access to the systems as the user account that the payload was executed as, either as an administrator or a regular user. Note that DeimosC2 does not perform active or privilege escalation of any kind.

The tag is: *misp-galaxy:malpedia="DeimosC2"*

DeliveryCheck

According to CERT-UA, this malware makes use of XSLT (Extensible Stylesheet Language Transformations) and COM-hijacking. Its specificity is the presence of a server part, which is usually installed on compromised MS Exchange servers in the form of a MOF (Managed Object Format) file using the Desired State Configuration (DCS) PowerShell tool), effectively turning a legitimate server into a malware control center.

The tag is: *misp-galaxy:malpedia="DeliveryCheck"*

DeliveryCheck is also known as:

- CAPIBAR
- GAMEDAY

https://malpedia.caad.fkie.fraunhofer.de/details/win.dented

Deprimon

According to ESET Research, DePriMon is a malicious downloader, with several stages and using many non-traditional techniques. To achieve persistence, the malware registers a new local port monitor – a trick falling under the “Port Monitors” technique in the MITRE ATT&CK knowledgebase. For that, the malware uses the “Windows Default Print Monitor” name; that’s why we have named it DePriMon. Due to its complexity and modular architecture, researcher believe it to be a framework.

DePriMon has been active since at least March 2017. DePriMon was detected in a private company, based in Central Europe, and at dozens of computers in the Middle East.

The tag is: *misp-galaxy:malpedia="Deprimon"*

Derusbi (Windows)

```
A DLL backdoor also reported publicly as Derusbi, capable of obtaining directory,
file, and drive listing; creating a reverse shell; performing screen captures;
recording video and audio; listing, terminating, and creating processes; enumerating,
starting, and deleting registry keys and values; logging keystrokes, returning
usernames and passwords from protected storage; and renaming, deleting, copying,
moving, reading, and writing to files.
```

DesertBlade

According to Microsoft, this was used in a limited destructive malware attack in early March 2022 impacting a single Ukrainian entity. DesertBlade is responsible for iteratively overwriting and then deleting overwritten files on all accessible drives (sparing the system if it is a domain controller).

The tag is: *misp-galaxy:malpedia="DesertBlade"*

DesertBlade is also known as:

Table 3680. Table References

DevilsTongue

According to Microsoft, DevilsTongue is a complex modular multi-threaded piece of malware written in C and C++ with several novel capabilities. For files on disk, PDB paths and PE timestamps are scrubbed, strings and configs are encrypted, and each file has a unique hash. The main functionality resides in DLLs that are encrypted on disk and only decrypted in memory, making detection more difficult. Configuration and tasking data is separate from the malware, which

makes analysis harder. DevilsTongue has both user mode and kernel mode capabilities.

The tag is: *misp-galaxy:malpedia="DevilsTongue"*

DEVMAN

DEVMAN is a ransomware which shares a large part of its codebase with DragonForce ransomware. It is highly probable that the group used a DragonForce ransomware build and simply changed the extension added to the encrypted files (from .dragonforce_encrypted to .devman). In one of the first observed samples, the ransom note still claimed to be part of the DragonForce Ransomware Cartel.

The ransomware implements common features such as the deletion of ShadowCopies, and avoid encrypting files with some extensions present in a hard-coded list. The ransomware implements multiple encryption modes:

- Full encryption
- Header-only encryption
- Custom encryption

These modes allow the operator to choose between a quick or a strong encryption depending on the scenario. The ransomware also tries to connect to SMB folders.

DEVMAN ransomware creates a temporary session under the following registry key: `HKEY_CURRENT_USER\Software\Microsoft\RestartManager\Session0000`. The use of the Restart Manager to bypass file locks and ensure encrypted access to active user session files. This capability seems to be a legacy of Conti ransomware, which inspired DragonForce and DEVMAN. As part of this legacy, the ransomware use a hard-coded mutex to prevent multiple instances from running in parallel.

The tag is: *misp-galaxy:malpedia="DEVMAN"*

Dharma

According to MalwareBytes, the Dharma Ransomware family is installed manually by attackers hacking into computers over Remote Desktop Protocol Services (RDP). The attackers will scan the Internet for computers running RDP, usually on TCP port 3389, and then attempt to brute force the password for the computer.

Once they gain access to the computer they will install the ransomware and let it encrypt the computer. If the attackers are able to encrypt other computers on the network, they will attempt to do so as well.

The tag is: *misp-galaxy:malpedia="Dharma"*

Dharma is also known as:

- Arena
- Crysis
- Wadhrama
- ncov

DiamondFox

According to PCrisk, DiamondFox is highly modular malware offered as malware-as-a-service, and is for sale on various hacker forums. Therefore, cyber criminals who are willing to use DiamondFox do not necessarily require any technical knowledge to perform their attacks.

Once purchased, this malware can be used to log keystrokes, steal credentials (e.g., usernames, email addresses, passwords), hijack cryptocurrency wallets, perform distributed denial of service (DDoS) attacks, and to carry out other malicious tasks.

DiamondFox allows cyber criminals to choose which plug-ins to keep activated and see infection statistics in real-time.

DMSniff

DMSniff is a point-of-sale malware previously only privately sold. It has been used in breaches of small- and medium-sized businesses in the restaurant and entertainment industries. It uses a domain generation algorithm (DGA) to create lists of command-and-control domains on the fly.

The tag is: *misp-galaxy:malpedia="DMSniff"*

DMSniff is also known as:

Table 3708. Table References

https://www.flashpoint-intel.com/blog/dmsniff-pos-malware-actively-leveraged-target-medium-sized-businesses/

DneSpy

DneSpy collects information, takes screenshots, and downloads and executes the latest version of other malicious components in the infected system. The malware is designed to receive a “policy” file in JSON format with all the commands to execute. The policy file sent by the C&C server can be changed and updated over time, making dneSpy flexible and well-designed. The output of each

executed command is zipped, encrypted, and exfiltrated to the C&C server. These characteristics make dneSpy a fully functional espionage backdoor.

Minodo

Since late February 2023, Minodo Backdoor campaigns have been employed to deliver either the Project Nemesis information stealer or more sophisticated backdoors like Cobalt Strike. This backdoor collects basic system information, which it then transmits to the C2 server. In return, it receives an AES-encrypted payload. Notably, the Minodo Backdoor is designed to contact a different C2 address for domain-joined systems. This suggests that more capable backdoors, such as Cobalt Strike, are downloaded on higher-value targets instead of Project Nemesis.

Dosia

Infrastructure and programs used for, as its name suggests, DDoSing. It used to be written in Python, nowadays it's written in Go. Clients:

- Are written in Go. (Used to be written in Python.)
- Do not seem to differ significantly across OS deployments. (Confirmed on Windows, MacOS, Linux, Android)
- Seem to be partly run by NoName themselves.
- Partly also run voluntarily, recruited via dedicated Telegram channels. Participants are rewarded with cryptocurrency. Prints a suggestion to use a VPN for Russia-based launches. (This yields IP-based blocking as rather ineffective, consider behavioral analysis instead.)

Configuration:

- Rotates near-daily. Can be browsed on https://witha.name/ (also reachable via http://withanamemwesdvodfhthjq25a5a3uas24cpgoa7qm6gchcerzpis6qd.onion/).
- Is sent encrypted between C2 and Client.
- Specifies target hostname, subpath, vector protocols, methods, ports, whether SSL is used, headers for HTTP, request bodies.
- Any given config property can be randomly generated with per-use constraints.
- Is provided by a multi-level hierarchy of C2 servers.

The tag is: *misp-galaxy:malpedia="Dosia"*

Dosia is also known as:

- DDOSIA

DOUBLEBACK

DOUBLEBACK is a newly discovered fileless malware deployed as part of an attack campaign that took place in December 2020. The threat actors responsible for the operations are tracked as UNC2529 by researchers. According to their findings, DOUBLEBACK is the final payload delivered onto the compromised systems. Its task is to establish and maintain a backdoor on the victim's machine.

DreamBot

2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*) 2014 Dreambot (Gozi ISFB variant)

In 2014, a variant of Gozi ISFB was developed. Mainly, the dropper performs additional anti-vm checks (vmware, vbox, qemu), while the actual bot-dll remains unchanged in most parts. New functionality, such as TOR support, was added though and often, the Fluxxy fast-flux network is used.

See win.gozi for additional historical information.

Dridex

OxCERT blog describes Dridex as "an evasive, information-stealing malware variant; its goal is to acquire as many credentials as possible and return them via an encrypted tunnel to a Command-and-Control (C&C) server. These C&C servers are numerous and scattered all over the Internet, if the malware cannot reach one server it will try another. For this reason, network-based measures such as blocking the C&C IPs is effective only in the short-term." According to MalwareBytes, "Dridex uses an older tactic of infection by attaching a Word document that utilizes macros to install malware. However, once new versions of Microsoft Office came out and users generally updated, such a threat subsided because it was no longer simple to infect a user with this method." IBM X-Force discovered "a new version of the Dridex banking Trojan that takes advantage of a code injection technique called AtomBombing to infect systems. AtomBombing is a technique for injecting malicious code into the 'atom tables' that almost all versions of Windows uses to store certain application data. It is a variation of typical code injection attacks that take advantage of input validation errors to insert and to execute malicious code in a legitimate process or application. Dridex v4 is the first malware that uses the AtomBombing process to try and infect systems."

Drokbk

Drokbk stands out for its use of the GitHub platform as part of its C&C infrastructure. This makes it difficult to detect and remove, as GitHub is not traditionally associated with malicious activities.

Drokbk attacks have been linked to the Iranian APT group Nemesis Kitten. This group is believed to use Drokbk for cyberespionage and financial information theft activities.

DUSTMAN

In 2019, multiple destructive attacks were observed targeting entities within the Middle East. The National Cyber Security Centre (NCSC), a part of the National Cybersecurity Authority (NCA), detected a new malware named "DUSTMAN" that was detonated on December 29, 2019. Based on analyzed evidence and artifacts found on machines in a victim's network that were not wiped by the malware. NCSC assess that the threat actor behind the attack had some kind of urgency on executing the files on the date of the attack due to multiple OPSEC failures observed on the infected network. NCSC is calling the malware used in this attack "DUSTMAN" after the filename and string embedded in the malware. "DUSTMAN" can be considered as a new variant of "ZeroCleare" malware, published in December 2019.

Dyre

The Dyre Banking Trojan, discovered in June 2014, targets online banking websites for credential theft and fraud. It uses a man-in-the-browser approach, encryption, and spam emails for distribution.

Dyre's architecture includes a dropper and main DLL module, with techniques for persistence and

evasion. Its command and control infrastructure is hidden through proxies, and it can adapt using a domain generation algorithm and I2P integration. Researchers have linked Dyre to the Gozi and Neverquest families.

Easy Stealer

Easy Stealer is a new information stealer written in Golang that is under active development. Since July 2023, the information stealer has been sold on the underground market, advertising a variety of capabilities, such as the ability to target crypto wallets and passwords. Based on VirusTotal data, it appears that developer test samples were uploaded in June 2023. The panel for the stealer is installed on the buyer's own infrastructure, allowing for exclusive control. The stated pricing models are: $35 for 7 days, $115 for 30 days, and $250 for 90 days. Given its user-friendly panel design and the affordable price range, combined with similar capabilities to other information stealers, Easy Stealer is likely to see an increase in distribution among various cyber criminals as it continues through active development.

EDA2

EDA2 is a successor of HiddenTear. Just like HiddenTear it was developed as an open-source project by a security researcher and published on Github. It was meant as "educational ransomware" and purposefully had flaws in the encryption process that allow decryption of ransomed files.

This backfired, when threat actors began to modify HiddenTear and EDA2 source code. Some modifications introduced bugs where encrypted files were destroyed, others fixed the encryption flaws and made decryption without a key impossible.

The tag is: *misp-galaxy:malpedia="EDA2"*

EDA2 is also known as:

ELECTRICFISH

The application is a command-line utility and its primary purpose is to tunnel traffic between two IP addresses. The application accepts command-line arguments allowing it to be configured with a destination IP address and port, a source IP address and port, a proxy IP address and port, and a user name and password, which can be utilized to authenticate with a proxy server. It will attempt to establish TCP sessions with the source IP address and the destination IP address. If a connection is made to both the source and destination IPs, this malicious utility will implement a custom protocol, which will allow traffic to rapidly and efficiently be tunneled between two machines. If necessary, the malware can authenticate with a proxy to be able to reach the destination IP address. A configured proxy server is not required for this utility.

Elirks

Elirks is a basic backdoor Trojan, first discovered in 2010, that is primarily used to steal

information from compromised systems. Mostly attacks using Elirks occurring in East Asia. One of the unique features of the malware is that it retrieves its C2 address by accessing a pre-determined microblog service or SNS. Attackers create accounts on those services and post encoded IP addresses or the domain names of real C2 servers in advance of distributing the backdoor. Multiple Elirks variants using Japanese blog services for the last couple of years.

ELMER

ELMER is a non-persistent proxy-aware HTTP backdoor written in Delphi, and is capable of performing file uploads and downloads, file execution, and process and directory listings. To retrieve commands, ELMER sends HTTP GET requests to a hard-coded CnC server, and parses the HTTP response packets received from the CnC server for an integer string corresponding to the command that needs to be executed.

Emmenhtal

Emmenhtal is a malicious loader likely distributed since early 2024, and publicly detailed by Orange Cyberdefense CERT in August 2024. Emmenhtal is an obfuscated multistage payload that spawns an execution of the LOLBIN mshta.exe to read a first HTA stage that embeds a malicious JavaScript code. Once interpreted and executed, the JavaScript decodes and runs a PowerShell script. The latter decrypts an obfuscated PowerShell loader which finally downloads and runs final-stage stealers and commodity RATs.

As of March 2025, Orange Cyberdefense CERT has identified three versions of the loader, all actively distributed.

The tag is: *misp-galaxy:malpedia="Emmenhtal"*

Emmenhtal is also known as:

Emotet

While Emotet historically was a banking malware organized in a botnet, nowadays Emotet is mostly seen as infrastructure as a service for content delivery. For example, since mid 2018 it is used by Trickbot for installs, which may also lead to ransomware attacks using Ryuk, a combination observed several times against high-profile targets. It is always stealing information from victims but what the criminal gang behind it did, was to open up another business channel by selling their infrastructure delivering additional malicious software. From malware analysts it has been classified into epochs depending on command and control, payloads, and delivery solutions which change over time. Emotet had been taken down by authorities in January 2021, though it appears to have sprung back to life in November 2021.

The tag is: *misp-galaxy:malpedia="Emotet"*

Emotet is also known as:

- Geodo
- Heodo

Epsilon Stealer

Epsilon Stealer is an information stealer sold as Malware as a Service by a new french actor called "Epsilon". This malware is distributed as a game, mainly on discord, but steals user credentials, crypto wallets, and stored cookies. It evades static detection by being packed with NSIS, which then launches a malicious Electron package.

EvilConwi

EvilConwi is a malicious variant of the legitimate ScreenConnect software by ConnectWise. This software is a remote access software. Threat actors modify the configuration extensively so that any signs of an active remote connection are removed. EvilConwi often pretends to perform a Windows update by using fake Windows update images embedded in the config. The purpose is to keep the system running while the threat actor connect remotely.

Other EvilConwi signs are fake application icons. E.g., it may pretend to be an installer for Zoom and use its icons and application titles in the ConnectWise config.

Exorcist

According to PCrisk, Exorcist is a ransomware-type malicious program. Systems infected with this malware experience data encryption and users receive ransom demands for decryption. During the encryption process, all compromised files are appended with an extension consisting of a ransom string of characters.

For example, a file originally named "1.jpg" could appear as something similar to "1.jpg.rnyZoV" following encryption. After this process is complete, Exorcist ransomware changes the desktop wallpaper and drops HTML applications - "[random-string]-decrypt.hta" (e.g. "rnyZoV-decrypt.hta") - into affected folders. These files contain identical ransom messages.

The tag is: *misp-galaxy:malpedia="Exorcist"*

Exorcist is also known as:

Expiro

Expiro malware has been around for more than a decade, and the malware authors sill continue their work and update it with more features. Also the infection routine was changed in samples fround in 2017 (described by McAfee). Expiro "infiltrates" executables on 32- and 64bit Windows OS versions. It has capabilities to install browser extensions, change security behaviour/settings on the infected system, and steal information (e.g. account credentials). There is a newly described EPO file infector source code called m0yv in 2022, which is wrongly identified as expiro by some AVs.

The tag is: *misp-galaxy:malpedia="Expiro"*

Expiro is also known as:

- Xpiro

Xtreme RAT

According to Trend MIcro, Extreme RAT (XTRAT, Xtreme Rat) is a Remote Access Trojan that can steal information. This RAT has been used in attacks targeting Israeli and Syrian governments last 2012.

This malware family of backdoors has the capability to receive commands such as File Management (Download, Upload, and Execute Files), Registry Management (Add, Delete, Query, and Modify Registry), Perform Shell Command, Computer Control (Shutdown, Log on/off), and Screen capture from a remote attacker. In addition, it can also log keystrokes of the infected systems.

The tag is: *misp-galaxy:malpedia="Xtreme RAT"*

FatalRat

FatalRAT is a most-likely chinese remote access tool distributed through forums and Telegram channels. FatalRAT executes various anti-virtual machine tests to avoid detection before fully infecting systems. Upon successful infiltration, it decrypts configuration strings, disables the CTRL+ALT+DELETE function, and activates a keylogger.

The malware can establish persistence via registry modifications or service creation, collect sensitive data, and communicate with its command and control (C&C) server using encrypted methods. FatalRAT also employs techniques like brute-force attacks against weak passwords to propagate within networks.

The tag is: *misp-galaxy:malpedia="FatalRat"*

FatalRat is also known as:

- Sainbox RAT

FatDuke

According to ESET Research, FatDuke is the current flagship backdoor of APT29 and is only deployed on the most interesting machines. It is generally dropped by the MiniDuke backdoor, but ESET also have seen the operators dropping FatDuke using lateral movement tools such as PsExec.The operators regularly repack this malware in order to evade detections. The most recent sample of FatDuke that ESET have seen was compiled on May 24, 2019. They have seen them trying to regain control of a machine multiple times in a few days, each time with a different sample.

Their packer, described in a later section, adds a lot of code, leading to large binaries. While the effective code should not be larger than 1MB, ESET have seen one sample weighing in at 13MB, hence our name for this backdoor component: FatDuke.

FDMTP

FDMTP is a newly discovered hacking tool developed in .NET, used by Earth Preta. It functions as a

simple malware downloader and is based on the TouchSocket framework over the Duplex Message Transport Protocol (DMTP). In one campaign, threat actors embedded FDMTP in the data section of a DLL. This allows it to be launched through DLL side-loading. The embedded network configurations are encoded and encrypted to enhance security and evade detection, utilizing Base64 and DES encryption methods. It has been observed to serve as a secondary control tool, often deployed by the PUBLOAD backdoor.

FinFisher RAT

FinFisher is a commercial software used to steal information and spy on affected victims. It began with few functionalities which included password harvesting and information leakage, but now it is mostly known for its full Remote Access Trojan (RAT) capabilities. It is mostly known for being used in governmental targeted and lawful criminal investigations. It is well known for its anti-detection capabilities and use of VMProtect.

FINTEAM

Recently, Check Point researchers spotted a targeted attack against officials within government finance authorities and representatives in several embassies in Europe. The attack, which starts with a malicious attachment disguised as a top secret US document, weaponizes TeamViewer, the popular remote access and desktop sharing software, to gain full control of the infected computer. This is achieved by sideloading another DLL among the legit TeamViewer.

The tag is: *misp-galaxy:malpedia="FINTEAM"*

FlawedAmmyy

FlawedAmmyy is a well-known Remote Access Tool (RAT) attributed to criminal gang TA505 and used to get the control of target machines. The name reminds the strong link with the leaked source code of Ammyy Admin from which it took the main structure.

The tag is: *misp-galaxy:malpedia="FlawedAmmyy"*

FlawedAmmyy is also known as:

Flesh Stealer

According to M4lcode, FleshStealer is a sophisticated, modular, and obfuscated .NET-based information-stealing malware designed for comprehensive data exfiltration from Windows systems. Its architecture is built for scale and stealth, utilizing multithreading to simultaneously run multiple data harvesting routines with minimal system disruption. The malware targets a wide range of applications and services, including browsers, messaging apps, email clients, VPNs, cryptocurrency wallets, FTP clients, game launchers, and local file storage.

FudModule

FudModule is a user-mode DLL that gets the ability to read and write arbitrary kernel memory via the BYOVD technique. Its main goal is to turn off Windows system monitoring features, which is done by modifying kernel variables and removing kernel callbacks. Its actions may very likely affect various types of security products, e.g. EDRs, firewalls, antimalware and even digital forensics tools.

FuwuqiDrama

FuwuqiDrama is a server-side RAT. It manages client connections by utilizing I/O completion ports, which are usually used in high-performance server applications as an elegant solution to manage

many clients at once.

It contains two distinguishing hardcoded lists.

First is a list of ~50 video files of South Korean TV series, having their titles translated to Mandarin Chinese, but encoded in the form of Pinyin romanization. That means the sounds are spelled in Latin alphabet without tone marks, for example meiyounihuobuxiaqu.avi represents Can't Live Without You (a K-drama from 2012) or wulalafufu.avi translates to Ohlala Couple (also from 2012).

Second is the list of the following corporations: NVIDIA, Amazon, Intel, Skype, 360Safe, Rising, Tencent, Mozilla, Adobe, Yahoo, Google. The same list is contained in some of the WannaCryptor samples.

FuwuqiDrama stores its configuration in the INI file data\package_con_x86.cat. It contains the port number and a bot identifier, all within a single section called Fuwuqi – the romanized Chinese word for server.

GaboonGrabber

According to ANY.RUN, the GaboonGrabber is a malware developed in .NET that grabs its embedded resources to prepare multiple fileless stages. Additionally, it has the tendency to camouflage itself as a legitimate application, going so far as to mimic legitimate applications in its

decompiled code. It also includes a steganographic image used to prepare further payloads.

GaboonGrabber's final stage can deploy various types of malware, including Snake Keylogger, AgentTesla, Redline, Lokibot, and more.

GAMYBEAR

GAMYBEAR

A software tool developed using the Go programming language. Its main functionality is to receive (“listener”), execute (‘executor’) commands, and send (“sender”) results to the control server in BASE64-encoded form using the HTTP protocol.

When launched, it generates a unique identifier (UUID), receives basic information about the computer (“whoami”, “wmic nicconfig where IPEnabled=true get IPAddress”), creates a helper file %APPDATA%\ updater.json, where the URL of the control server is stored in JSON format (key “update_server”), as well as other listed data in BASE64-encoded form (keys: “uuid”, ‘hostname’, “ip”, respectively).

During operation, the software regularly sends requests to the control server (URI: “/c2/get_commands/”) and waits for a response in JSON format with the ‘command’ and “arguments” fields. If the “Nop” command is received, a 15-second pause is initiated. After the commands are executed, the result and other data are encoded using BASE64, stored in a JSON structure (keys: “uuid”, “command”, ‘output’) and sent to the control server with a request to the URI “/c2/command_out/”.

The consistency of the launch is ensured by another program (script) at the stage of the initial infection of the computer by creating a key in the “Run” branch of the operating system registry.

Gandcrab

GandCrab was a Ransomware-as-a-Service (RaaS) emerged in January 28, 2018, managed by a criminal organization known to be confident and vocal, while running a rapidly evolving ransomware campaign. Through their aggressive, albeit unusual, marketing strategies and constant recruitment of affiliates, they were able to globally distribute a high volume of their malware.

In a surprising announcement on May 31, 2019, the GandCrab's operators posted on a dark web forum, announced the end of a little more than a year of ransomware operations, citing staggering profit figures. However, If there's one thing that sets these threat actors apart from other groups, it is that they are unpredictable; so there is always the possibility that they might re-surface in one form or another.

The tag is: *misp-galaxy:malpedia="Gandcrab"*

Gandcrab is also known as:

- GrandCrab

GhostSocks

GhostSocks, a Golang-based proxy malware, was first advertised as a Malware-as-a-Service (MaaS) on Russian-speaking underground forums in October 2023. It uses back-connect socket secure internet protocol (SOCKS5) connections and is available for rent for US $100 per month. In February 2024, the author of Lumma Stealer released an update introducing the integration of proxying capabilities. This feature, developed in partnership with GhostSocks, allows the use of infected hosts as SOCKS5 proxies and is available to all subscribers who purchase the "Professional" or higher tier plan. This integration allows Lumma Stealer users to establish a network of residential IP addresses for various purposes, including credential checking, spam distribution, or as general-purpose proxies.

Ghost RAT

According to Security Ninja, Gh0st RAT (Remote Access Terminal) is a trojan “Remote Access Tool” used on Windows platforms, and has been used to hack into some of the most sensitive computer networks on Earth.

Below is a list of Gh0st RAT capabilities. Take full control of the remote screen on the infected bot. Provide real time as well as offline keystroke logging. Provide live feed of webcam, microphone of infected host. Download remote binaries on the infected remote host. Take control of remote shutdown and reboot of host. Disable infected computer remote pointer and keyboard input. Enter into shell of remote infected host with full control. Provide a list of all the active processes. Clear all existing SSDT of all existing hooks.

GlobeImposter

GlobeImposter is a ransomware application which is mainly distributed via "blank slate" spam (the spam has no message content and an attached ZIP file), exploits, malicious advertising, fake updates, and repacked installers. GlobeImposter mimics the Globe ransomware family. This malware may prevent execution of Anti-Virus solutions and other OS related security features and may prevent system restoration.

The tag is: *misp-galaxy:malpedia="GlobeImposter"*

GlobeImposter is also known as:

- Fake Globe

GodRAT

GodRAT shares a common origin with AwesomePuppet RAT, alongside Gh0st RAT code similarities. GodRAT is likely connected with Winnty APT activities.

Old implant codebases, such as Gh0st RAT, which are nearly two decades old, continue to be used today. These are often customized and rebuilt to target a wide range of victims. These old implants are known to have been used by various threat actors for a long time, and the GodRAT discovery demonstrates that legacy codebases like Gh0st RAT can still maintain a long lifespan in the cybersecurity landscape.

GoldenSpy

According securityweek, GoldenSpy, the malware was observed as part of a campaign that supposedly started in April 2020, but some of the identified samples suggest the threat has been around since at least December 2016.

One of the compromised organizations, a global technology vendor that conducts government business in the US, Australia and UK, and which recently opened offices in China, became infected after installing “Intelligent Tax,” a piece of software from the Golden Tax Department of Aisino Corporation, which a local bank required for paying local taxes.

Although it worked as advertised, the software was found to install a hidden backdoor to provide remote operators with the possibility to execute Windows commands or upload and run files.

GoldMax

Gold Max is a Golang written command and control backdoor used by the NOBELIUM threat actor group. It uses several different techniques to obfuscate its actions and evade detection. The malware writes an encrypted configuration file to disk, where the file name and AES-256 cipher keys are unique per implant and based on environmental variables and information about the network where it is running.

The tag is: *misp-galaxy:malpedia="GoldMax"*

GoldMax is also known as:

- SUNSHUTTLE

GoldDragon

GoldDragon was a second-stage backdoor which established a permanent presence on the victim's system once the first-stage, file-less, PowerShell-based attack leveraging steganography was executed. The initial attack was observed first in December 2017, when a Korean-language spear phishing campaing targeted organizations linked with Pyeongchang Winter Olympics 2018. GoldDragon was delivered once the attacker had gained an initial foothold in the targeted environment.

The malware was capable of a basic reconnaissance, data exfiltration and downloading of additional components from its C&C server.

The tag is: *misp-galaxy:malpedia="GoldDragon"*

GoldDragon is also known as:

Gomorrah stealer

Gomorrah is a stealer with no or little obfuscation that appeared around March 2020. It is sold for about 150$ lifetime for v4 (originally 400$ for v3) or 100$ per month by its developer called "th3darkly / lucifer" (which is also the developer of CosaNostra botnet). The malware's main functionalities are stealing (passwords, cryptocurrency wallets) and loading of tasks and other payloads.

GootKit

Gootkit is a banking trojan consisting of an x86 loader and a payload embedding nodejs as well as a set of js scripts. The loader downloads the payload, stores it in registry and injects it in a copy of the loader process. The loader also contains two encrypted DLLs intended to be injected into each browser process launched in order to place the payload in man in the browser and allow it to apply the webinjects received from the command and control server on HTTPx exchanges. This allows Gootkit to intercept HTTPx requests and responses, steal their content or modify it according to the webinjects.

The tag is: *misp-galaxy:malpedia="GootKit"*

Gozi

2000 Ursnif aka Snifula 2006 Gozi v1.0, Gozi CRM, CRM, Papras 2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*) → 2010 Gozi Prinimalka → Vawtrak/Neverquest

In 2006, Gozi v1.0 ('Gozi CRM' aka 'CRM') aka Papras was first observed. It was offered as a CaaS, known as 76Service. This first version of Gozi was developed by Nikita Kurmin, and he borrowed code from Ursnif aka Snifula, a spyware developed by Alexey Ivanov around 2000, and some other kits. Gozi v1.0 thus had a formgrabber module and often is classified as Ursnif aka Snifula.

In September 2010, the source code of a particular Gozi CRM dll version was leaked, which led to Vawtrak/Neverquest (in combination with Pony) via Gozi Prinimalka (a slightly modified Gozi v1.0) and Gozi v2.0 (aka 'Gozi ISFB' aka 'ISFB' aka Pandemyia). This version came with a webinject module.

Grager

Grager is a backdoor deployed against three organizations in Taiwan, Hong Kong, and Vietnam in April 2024. Analysis of this backdoor revealed that it uses the Graph API to communicate with a command and control (C&C) server hosted on Microsoft OneDrive. The backdoor decrypts a client ID and refresh token for OneDrive from a blob contained within its file body. It supports the following commands:

- Retrieve machine information, including machine name, user, IP address, and machine architecture
- Download or upload a file

- Execute a file
- Gather file system information, including available drives, their sizes, and types of drives

Graphican

According to Symantec, Graphican is an evolution of the known APT15 backdoor Ketrican, which itself was based on a previous malware - BS2005 - also used by APT15. Graphican has the same basic functionality as Ketrican, with the difference between them being Graphican's use of the Microsoft Graph API and OneDrive to obtain its command-and-control (C&C) infrastructure.

Grateful POS

POS malware targets systems that run physical point-of-sale device and operates by inspecting the process memory for data that matches the structure of credit card data (Track1 and Track2 data), such as the account number, expiration date, and other information stored on a card's magnetic stripe. After the cards are first scanned, the personal account number (PAN) and accompanying data sit in the point-of-sale system's memory unencrypted while the system determines where to send it for authorization. Masked as the LogMein software, the GratefulPOS malware appears to have emerged during the fall 2017 shopping season with low detection ratio according to some of the earliest detections displayed on VirusTotal. The first sample was upload in November 2017. Additionally, this malware appears to be related to the Framework POS malware, which was linked to some of the high-profile merchant breaches in the past.

GRIMAGENT

GRIMAGENT is a backdoor that can execute arbitrary commands, download files, create and delete scheduled tasks, and execute programs via scheduled tasks or via the ShellExecute API. The malware persists via a randomly named scheduled task and a registry Run key. The backdoor communicates to hard-coded C&C servers via HTTP requests with portions of its network communications encrypted using both asymmetric and symmetric cryptography. GRIMAGENT was used during some Ryuk Ransomware intrusions in 2020.

Havex RAT

Havex is a remote access trojan (RAT) that was discovered in 2013 as part of a widespread

espionage campaign targeting industrial control systems (ICS) used across numerous industries and attributed to a hacking group referred to as "Dragonfly" and "Energetic Bear". Havex is estimated to have impacted thousands of infrastructure sites, a majority of which were located in Europe and the United States. Within the energy sector, Havex specifically targeted energy grid operators, major electricity generation firms, petroleum pipeline operators, and industrial equipment providers. Havex also impacted organizations in the aviation, defense, pharmaceutical, and petrochemical industries.

Once installed, Havex scanned the infected system to locate any Supervisory Control and Data Acquisition (SCADA) or ICS devices on the network and sent the data back to command and control servers. To do so, the malware leveraged the Open Platform Communications (OPC) standard, which is a universal communication protocol used by ICS components across many industries that facilitates open connectivity and vendor equipment interoperability. Havex used the Distributed Component Object Model (DCOM) to connect to OPC servers inside of an ICS network and collect information such as CLSID, server name, Program ID, OPC version, vendor information, running state, group count, and server bandwidth.

Havex was an intelligence-collection tool used for espionage and not for the disruption or destruction of industrial systems. However, the data collected by Havex would have aided efforts to design and develop attacks against specific targets or industries.

The tag is: *misp-galaxy:malpedia="Havex RAT"*

Havoc

First released in October 2022, the Havoc C2 Framework is a flexible post-exploitation framework written in Golang, C++, and Qt, with agents called 'Demons' written in C and ASM, created by @C5pider. Designed to support red team engagements and adversary emulation, it offers a robust set of capabilities tailored for offensive security operations. The framework, which is under active development, utilizes HTTP(s) and SMB as communication protocols for its implants. Havoc can generate implants, known as Demons, in several formats including EXE, DLL, and Shellcode. A notable feature of Havoc is its ability to bypass EDR by employing advanced evasion techniques such as sleep obfuscation, return address stack spoofing, and indirect syscalls. This capability

enhances its effectiveness in evading detection and circumventing security measures.

The tag is: *misp-galaxy:malpedia="Havoc"*

Havoc is also known as:

- Havokiz

HawkEye Keylogger

HawKeye is a keylogger that is distributed since 2013. Discovered by IBM X-Force, it is currently spread over phishing campaigns targeting businesses on a worldwide scale. It is designed to steal credentials from numerous applications but, in the last observed versions, new "loader capabilities" have been spotted. It is sold by its development team on dark web markets and hacking forums.

The tag is: *misp-galaxy:malpedia="HawkEye Keylogger"*

HawkEye Keylogger is also known as:

HelloKitty (Windows)

Unit42 states that HelloKitty is a ransomware family that first surfaced at the end of 2020, primarily targeting Windows systems. The malware family got its name due to its use of a Mutex with the same name: HelloKittyMutex. The ransomware samples seem to evolve quickly and frequently, with different versions making use of the .crypted or .kitty file extensions for encrypted files. Some newer samples make use of a Golang packer that ensures the final ransomware code is only loaded in memory, most likely to evade detection by security solutions.

The tag is: *misp-galaxy:malpedia="HelloKitty (Windows)"*

HelloKitty (Windows) is also known as:

- KittyCrypt

HermeticWiper

According to SentinelLabs, HermeticWiper is a custom-written application with very few standard functions. It abuses a signed driver called "empntdrv.sys" which is associated with the legitimate Software "EaseUS Partition Master Software" to enumerate the MBR and all partitions of all Physical Drives connected to the victims Windows Device and overwrite the first 512 Bytes of every MBR and Partition it can find, rendering them useless. This malware is associated to the malware attacks against Ukraine during Russians Invasion in February 2022.

The tag is: *misp-galaxy:malpedia="HermeticWiper"*

HermeticWiper is also known as:

- DriveSlayer
- FoxBlade
- KillDisk.NCV
- NEARMISS

HiddenTear

HiddenTear is an open source ransomware developed by a Turkish programmer and later released as proof of concept on GitHub. The malware generates a local symmetric key in order to encrypt a configurable folder (/test was the default one) and it sends it to a centralized C&C server. Due to its small payload it was used as real attack vector over email phishing campaigns. Variants are still used in attacks.

The tag is: *misp-galaxy:malpedia="HiddenTear"*

HiddenTear is also known as:

HILDACRYPT

A new ransomware family was discovered in August 2019. Called HILDACRYPT, it is named after the Netflix cartoon “Hilda” because the TV show’s YouTube trailer was included in the ransom note of the original version of the malware.

Hive (Windows)

Hive is a strain of ransomware that was first discovered in June 2021. Hive was designed to be used by Ransomware-as-a-service providers, to enable novice cyber-criminals to launch ransomware attacks on healthcare providers, energy providers, charities, and retailers across the globe. In 2022 there was a switch from GoLang to Rust.

Hunters International

Emerging in Q3 2023 as a Ransomware-as-a-Service (RaaS) operation, Hunters International has established itself as a distinct yet controversial threat actor in the cybercrime ecosystem. While initial analysis revealed a code overlap with the dismantled Hive ransomware, the group claims independence, asserting it purchased Hive's source code rather than directly rebranding. This operational lineage enables advanced double-extortion campaigns prioritizing data exfiltration over encryption, with confirmed theft of medical records, financial data, and proprietary business information. The group's ransomware is written in Rust, a programming language favored for its resilience to reverse engineering and cross-platform compatibility.

HyperBro

HyperBro is a RAT that has been observed to target primarily within the gambling industries, though it has been spotted in other places as well. The malware typically consists of 3 or more components: a) a genuine loader typically with a signed certification b) a malicious DLL loader loaded from the former component via DLL hijacking c) an encrypted and compressed blob that decrypts to a PE-based payload which has its C2 information hardcoded within.

I2PRAT

According to Cofense, this malware is notable for having several unique tactics, techniques, and procedures (TTPs), such as Secure Email Gateway (SEG) evasion by proxying emails through legitimate infrastructure, fake CAPTCHAs, abusing hardcoded Windows functionality to hide dropped files, and C2 capabilities over Invisible Internet Project (I2P), a peer-to-peer anonymous network with end-to-end encryption. Upon installation, I2Parcae is capable of disabling Windows Defender, enumerating Windows Security Accounts Manager (SAM) for accounts/groups, stealing browser cookies, and remote access to infected hosts. As of November 2024, I2Parcae appears to be delivered via automated spam messages targeting customer support contact forms on multiple websites. The messages deliver an embedded link purporting to be pornography.

IcedID

According to Proofpoint, IcedID (aka BokBot) is a malware originally classified as a banking malware and was first observed in 2017. It also acts as a loader for other malware, including ransomware. The well-known IcedID version consists of an initial loader which contacts a Loader C2 server, downloads the standard DLL Loader, which then delivers the standard IcedID Bot. IcedID is developed and operated by the actor named LUNAR SPIDER.

As previously published, historically there has been just one version of IcedID that has remained constant since 2017. * In November 2022, Proofpoint researchers observed the first new variant of IcedID Proofpoint dubbed 'IcedID Lite' distributed as a follow-on payload in a TA542 Emotet campaign. It was dropped by the Emotet malware soon after the actor returned to the e-crime landscape after a nearly four-month break. * The IcedID Lite Loader observed in November 2022 contains a static URL to download a 'Bot Pack' file with a static name (botpack.dat) which results in the IcedID Lite DLL Loader, and then delivers the Forked version of IcedID Bot, leaving out the webinjects and backconnect functionality that would typically be used for banking fraud. * Starting in February 2023, Proofpoint observed the new Forked variant of IcedID. This variant was distributed by TA581 and one unattributed threat activity cluster which acted as initial access facilitators. The campaigns used a variety of email attachments such as Microsoft OneNote attachments and somewhat rare to see .URL attachments, which led to the Forked variant of IcedID.

The tag is: *misp-galaxy:malpedia="IcedID"*

IcedID is also known as:

- BokBot
- IceID

win.icexloader

IceXLoader is a commercial malware used to download and deploy additional malware on infected

machines. The latest version is written in Nim, a relatively new language utilized by threat actors the past two years, most notably by the NimzaLoader variant of BazarLoader used by the TrickBot group.

The v1 was written in AutoIT.

Ice IX

The ICE IX bot is a banking trojan derived of the Zeus botnet because it uses significant parts of Zeus's source code. ICE IX communicates using the HTTP protocol, so it can be considered to be a

third-generation botnet. While it has been used for a variety of purposes, a primary threat of ICE IX comes from its manipulation of banking operations on compromised machines. As with any bot, execution of the bot results in establishing a master-slave relationship between the botmaster and the compromised computer.

ImprudentCook

ImprudentCook is an HTTP(S) downloader.

It was delivered in the Operation DreamJob type of activity targeting aerospace and defense companies in South Africa (in Q2 2022) and in Central Europe (in H1 2023), and against an unknown sector in South Korea back in Q2 2021.

It uses the AES cipher implemented through Windows Cryptographic Providers for decryption of its binary configuration, and also for encryption and decryption of the client-server communication.

It's hidden in an ADS stream (:dat or :zone) of its dropper, together with its configuration (:rsrc) and an AES-128 CBC key with an initialization vector for its decryption (:kgb or :data).

It contains two characteristic arrays of strings that represent cookie names for web services, including Bing, Daum and GitHub:

1. iKc;*uid;OAX;DMP_UID;PCID;_gid;_gat;csrftoken;NID;1P_JAR;JSESSIONID;WLS;SNID;* utma;BID;SRCHD;GsCK_AC;spintop;eader;XSRF-TOKEN;_gat_gtag_UA;webid_enabled;EDGE_V;dtck_channel;dtmulti;UUID;XUID;ZIA;IUID;SSID;_gh_sess;_octo
2. channel;post_titles;xfw_exp;wiht_clkey;SGPCOUPLE;NRTK;fbp;uaid;SRCHUSR;GUC;HPVN;dtck_blog;dtck_media;MUIDB;SRCHHPGUSR;SiteMain

It contains a string, "5.40" or "5.60", looking like version information.

INCONTROLLER

INCONTROLLER (aka PIPEDREAM) is a set of tools built to target machine automation devices. The tools can interact with specific industrial equipment embedded in different types of machinery leveraged across multiple industries. This tool set is very likely state sponsored and contains capabilities related to disruption, sabotage, and potentially physical destruction.

The tag is: *misp-galaxy:malpedia="INCONTROLLER"*

INCONTROLLER is also known as:

InfinityLock

InfinityLock ransomware is a type of malicious software that encrypts a victim's files and demands a ransom payment in order to decrypt them. It is spread through phishing emails and malicious websites. Once a computer is infected with InfinityLock, it encrypts all important files, such as documents, photos, and videos. It then displays a message that demands the victim pay a ransom of

$1,000 in Bitcoin in order to decrypt the files. If the victim does not pay the ransom, the files will be lost permanently.

InnaputRAT

InnaputRAT, a RAT capable of exfiltrating files from victim machines, was distributed by threat actors using phishing and Godzilla Loader. The RAT has evolved through multiple variants dating back to 2016. Recent campaigns distributing InnaputRAT beaconed to live C2 as of March 26, 2018.

win.innfirat

InnifiRAT is coded in .NET and targets personal data on infected devices, with it's top priority appearing to be bitcoin and litecoin wallet data.

InffiRAT also includes a backdoor which allows attackers to control the infected host remotely. Possibilities include loggin key stroke, taking pictures with webcam, accessing confidential information, formatting drives, and more.

It attempts to steal browser cookies to steal usernames and passwords and monitors the users activities with screenshot functionality.

InvisiMole

InvisiMole had a modular architecture, starting with a wrapper DLL, and performing its activities using two other modules that were embedded in its resources, named RC2FM and RC2CL. They were feature-rich backdoors and turned the affected computer into a video camera, letting the attackers to spy the victim. The malicious actors behind this malware were active at least since 2013 in highly targeted campaigns with only a few dozen compromised computers in Ukraine and Russia. The wrapper DLL posed as a legitimate mpr.dll library and was placed in the same folder as explorer.exe, which made it being loaded during the Windows startup into the Windows Explorer process instead of the legitimate library. Malware came in both 32-bit and 64-bit versions, which made this persistence technique functional on both architectures.

The smaller of the modules, RC2FM, contained a backdoor with fifteen supported commands indexed by numbers. The commands could perform simple changes on the system and spying features like capturing sounds, taking screenshots or monitoring all fixed and removable drives.

The second module, RC2CL, offered features for collecting as much data about the infected computer as possible, rather than for making system changes. The module supported up to 84 commands such as file system operations, file execution, registry key manipulation, remote shell activation, wireless network scanning, listing of installed software etc. Though the backdoor was capable of interfering with the system (e.g. to log off a user, terminate a process or shut down the system), it mostly provided passive operations. Whenever possible, it tried to hide its activities by restoring the original file access time or safe-deleting its traces.

IRONHALO

```
IRONHALO is a downloader that uses the HTTP protocol to retrieve a Base64 encoded
payload from a hard-coded command-and-control (CnC) server and uniform resource
locator (URL) path.
The encoded payload is written to a temporary file, decoded and executed in a hidden
window. The encoded and decoded payloads are written to files named igfxHK[%rand%].dat
and igfxHK[%rand%].exe respectively, where [%rand%] is a 4-byte hexadecimal number
based on the current timestamp. It persists by copying itself to the current user
Startup folder.

ISFB

2006 Gozi v1.0, Gozi CRM, CRM, Papras 2010 Gozi v2.0, Gozi ISFB, ISFB, Pandemyia(*)

In September 2010, the source code of a particular Gozi CRM dll version was leaked. This led to two main branches: one became known as Gozi Prinimalka, which was merge with Pony and became Vawtrak/Neverquest.

The other branch became known as Gozi ISFB, or ISFB in short. Webinject functionality was added to this version.

There is one panel which often was used in combination with ISFB: IAP. The panel's login page comes with the title 'Login - IAP'. The body contains 'AUTHORIZATION', 'Name:', 'Password:' and a single button 'Sign in' in a minimal design. Often, the panel is directly accessible by entering the C2 IP address in a browser. But there are ISFB versions which are not directly using IAP. The bot accesses a gate, which is called the 'Dreambot' gate. See win.dreambot for further information.

ISFB often was protected by Rovnix. This led to a further complication in the naming scheme - many companies started to call ISFB Rovnix. Because the signatures started to look for Rovnix, other trojans protected by Rovnix (in particular ReactorBot and Rerdom) sometimes got wrongly labelled.

In April 2016 a combination of Gozi ISFB and Nymaim was detected. This breed became known as GozNym. The merge uses a shellcode-like version of Gozi ISFB, that needs Nymaim to run. The C2 communication is performed by Nymaim.

See win.gozi for additional historical information.

The tag is: *misp-galaxy:malpedia="ISFB"*

ISFB is also known as:

- Gozi ISFB
- IAP
- Pandemyia

ISR Stealer

ISR Stealer is a modified version of the Hackhound Stealer. It is written in VB and often comes in a .NET-wrapper. ISR Stealer makes use of two Nirsoft tools: Mail PassView and WebBrowserPassView.

Incredibly, it uses an hard-coded user agent string: HardCore Software For : Public

JanelaRAT

According to Zscaler, JanelaRAT is a heavily modified variant of BX RAT. Its focus is set on harvesting LATAM financial data and its method of extracting window titles for transmission underscores its targeted and stealthy nature. With an adaptive approach utilizing dynamic socket configuration and exploiting DLL side-loading from trusted sources, JanelaRAT poses a significant threat.

jason

Jason is a graphic tool implemented to perform Microsoft exchange account brute-force in order to “harvest” the highest possible emails and accounts information. Distributed in a ZIP container the interface is quite intuitive: the Microsoft exchange address and its version shall be provided. Three brute-force methods could be selected: EWS (Exchange Web Service), OAB (Offline Address Book) or both (All). Username and password list can be selected and threads number should be provided in order to optimize the attack balance.

JessieConTea

JessieConTea is a remote access trojan that uses HTTP(S) for communication. It supports around 30 commands that include operations on the victim's filesystem, basic process management, file exfiltration (both plain and zipped), and the download and execution of additional tools from the attacker's arsenal. The commands are indexed by 32-bit integers, starting with the value 0x60D49D97.

The malware was delivered in-the-wild via trojanized applications like DeFi Wallet or Citrix Workspace.

JessieConTea generates POST parameters with a specific parameter name, jsessid, from which the

initial part of its name is derived. Also, it contains a specific RTTI symbol ".?AVCHttpConn@@", which inspired the second part of the name. It uses RC4 for C&C traffic encryption.

The tag is: *misp-galaxy:malpedia="JessieConTea"*

JhoneRAT

Cisco Talos identified JhoneRAT in January 2020. The RAT is delivered through cloud services (Google Drive) and also submits stolen data to them (Google Drive, Twitter, ImgBB, GoogleForms). The actors using JhoneRAT target Saudi Arabia, Iraq, Egypt, Libya, Algeria, Morocco, Tunisia, Oman, Yemen, Syria, UAE, Kuwait, Bahrain and Lebanon.

Kamasers

Kamasers is a DDOS botnet. The bot has backdoor capabilities as it connects to an attacker

controller C2 server. This allows it to download files, receive commands, and execute files, allowing it to perform HTTP and DNS flooding attacks. The bot is also used to access sensitive files.

The bot has been seen to be communicating with third-party platforms such as Telegram, Discord, and GitHub, using these platforms as backup C2 servers.

Kaolin RAT

Kaolin RAT is a complex modular RAT, with Release_TMain_x64.dll as its internal DLL name.

The malware provides standard backdoor functionality, including manipulation and listing of files and processes, exchanging the configuration, collecting the victim's system info, opening a TCP connection, and executing local commands and collecting their outputs.

Also, it is designed to execute additional DLL payloads in memory via specific exported functions: - _DoMyFunc, - _DoMyFunc2, - _DoMyThread, - _DoMyCommandWork.

Functionally, Kaolin RAT relies on an accompanying trojanized curl library to handle network and exfiltration operations, by importing functions such as: - SendDataFromURL, - ZipFolder, - UnzipStr, - curl wrappers.

For C&C communication, it employs AES encryption and attempts to evade network detection by randomly selecting words from a hardcoded custom dictionary to populate POST request

parameters. The malware's name is derived from one of these dictionary words ("kaolin").

The Kaolin RAT has been observed in Lazarus campaigns as a late-stage payload — typically following loaders like RollFling, RollSling, and RollMid — and serves also as a delivery vector for the FudModule rootkit with a 0-day exploit.

The tag is: *misp-galaxy:malpedia="Kaolin RAT"*

Kaolin RAT is also known as:

- KaolinTea

Kardon Loader

According to ASERT, Kardon Loader is a fully featured downloader, enabling the download and installation of other malware, eg. banking trojans/credential theft etc.This malware has been on sale by an actor under the username Yattaze, starting in late April. The actor offers the sale of the malware as a standalone build with charges for each additional rebuild, or the ability to set up a botshop in which case any customer can establish their own operation and further sell access to a new customer base.

The tag is: *misp-galaxy:malpedia="Kardon Loader"*

Karius

According to checkpoint, Karius is a banking trojan in development, borrowing code from Ramnit, Vawtrack as well as Trickbot, currently implementing webinject attacks only.

It comes with an injector that loads an intermediate "proxy" component, which in turn loads the actual banker component.

Communication with the c2 are in json format and encrypted with RC4 with a hardcoded key.

In the initial version, observed in March 2018, the webinjects were hardcoded in the binary, while in subsequent versions, they were received by the c2.

The tag is: *misp-galaxy:malpedia="Karius"*

KillDisk

KillDisk is a generic detection name used by ESET to refer to destructive malware with disk wiping capabilities, such as damaging boot sectors and overwriting then deleting (system) files, followed by a reboot to render the machine unusable. Although all KillDisk malware has similar functionality, as a generic detection, individual samples do not necessarily have strong code similarities or relationships. Such generic malware detections usually have many “sub-families”, distinguished by the detection suffix (e.g. KillDisk.NBO, KillDisk.NCV, and KillDisk.NCX). Sub-family variants that do have strong code similarities, are sometimes seen in separate cyberattacks and thus can help researchers make connections between them.

KiwiStealer

According to Threatray, KiwiStealer is a simple file stealer first discovered in late 2024. It starts by gathering the computer name and username. It also retrieves the current system time, which will be used later to check the last modification time of files on the machine. KiwiStealer searches through a predefined list of directories to gather files and only exfiltrates files that are smaller than 50MB and have been modified within the past year. It targets these extensions: z7, .txt, .doc, .docx, .xls, .xlsx, .ppt, .pptx, .pdf, .rtf, .jpg, .zip, .rar, .apk, .neat, .err, .eln, .ppi, .er9, .azr, .pfx, .ovpn.

KleptoParasite Stealer

KleptoParasite Stealer is advertised on Hackforums as a noob-friendly stealer. It is modular and comes with a IP retriever module, a Outlook stealer (32bit/64bit) and a Chrome/Firefox stealer (32bit/64bit). Earlier versions come bundled (loader plus modules), newer versions come with a loader (167k) that grabs the modules.

PDB-strings suggest a relationship to JogLog v6 and v7.

Koadic

Koadic is an open-source post-exploitation framework for Windows, created by zerosum0x0 and available on GitHub. The framework is written in Python and can generate JScript and VBScript payloads which can be written to disk or mapped directly into memory. Its capabilities include remote desktop access, command execution, lateral movement via SMB, file transfer, credential theft using Mimikatz, port scanning, and system information collection. It can also collect specific system information and targeted files based on their name or extension.

Krachulka

According to ESET, this malware family is a banking trojan and was active in Brazil until the middle of 2019. Its most noticeable characteristic was its usage of well-known cryptographic methods to encrypt strings, as opposed to the majority of Latin American banking trojans that mainly use custom encryption schemes.

Kronos

Kronos malware is a sophisticated banking Trojan that first emerged in 2014. It is designed to target financial institutions and steal sensitive banking information. The malware is primarily spread through phishing campaigns and exploit kits. Once installed on a victim's computer, Kronos can capture login credentials, credit card details, and other personal information by keylogging and form grabbing techniques. It can also bypass security measures such as two-factor authentication. Kronos employs advanced evasion techniques to avoid detection by antivirus software and actively updates itself to evade security patches. It has been known to target a wide range of banking systems and has affected numerous organizations worldwide. The malware continues to evolve, making it a significant threat to online banking security.

The tag is: *misp-galaxy:malpedia="Kronos"*

Kronos is also known as:

LambLoad

According to Microsoft, this is a downloader used in a supply chain attack involving a malicious variant of an application developed by CyberLink. It is centered around a legitimate CyberLink application installer that has been modified to include malicious code that downloads, decrypts, and loads a second-stage payload. The file, which was signed using a valid certificate issued to CyberLink Corp., is hosted on legitimate update infrastructure owned by CyberLink and includes checks to limit the time window for execution and evade detection by security products.

The tag is: *misp-galaxy:malpedia="LambLoad"*

LatentBot

FireEye describes this malware as a highly obfuscated bot that has been in the wild since mid-2013. It has managed to leave hardly any traces on the Internet, is capable of watching its victims without ever being noticed, and can even corrupt a hard disk, thus making a PC useless.

Using Dynamic Threat Intelligence, they have observed multiple campaigns targeting multiple industries in the United States, United Kingdom, South Korea, Brazil, United Arab Emirates, Singapore, Canada, Peru and Poland – primarily in the financial services and insurance sectors. Although the infection strategy is not new, the final payload dropped – which they named LATENTBOT – caught attention since it implements several layers of obfuscation, a unique exfiltration mechanism, and has been very successful at infecting multiple organizations.

Leslieloader

Leslieloader is a loader written in Golang, named after the observed AES decryption key referencing deceased actor, Leslie Cheung. The loader assists in the initial infection and deployment of the malicious payload, enabling execution on a system. The loader achieves its goal by decoding and decrypting a secondary payload binary, then injecting it into another process.

LightlessCan

LightlessCan is a complex HTTP(S) RAT, that is a successor of the Lazarus RAT named BlindingCan.

In Q2 2022 and Q1 2023, it was deployed in targeted attacks against an aerospace company in Spain and a technology company in India.

Besides the support for commands already present in BlindingCan, its most significant update is mimicked functionality of many native Windows commands: • ipconfig • net • netsh advfirewall firewall • netstat • reg • sc • ping (for both IPv4 and IPv6 protocols) • wmic process call create • nslookup • schstasks • systeminfo • arp

These native commands are often abused by the attackers after they have gotten a foothold in the target's system. Lightless is able to execute them discreetly within the RAT itself, rather than being executed visibly in the system console. This provides stealthiness, both in evading real-time monitoring solutions like EDRs, and postmortem digital forensic tools.

LightlessCan use RC6 for decryption of its configuration, and also for encryption and decryption of network traffic.

The tag is: *misp-galaxy:malpedia="LightlessCan"*

LightlessCan is also known as:

- SIDESHOW

LimeRAT

```
## Description
Simple yet powerful RAT for Windows machines. This project is simple and easy to
understand, It should give you a general knowledge about dotNET malwares and how it
behaves.
```

Main Features

- **.NET**
- Coded in Visual Basic .NET, Client required framework 2.0 or 4.0 dependency, And server is 4.0
- **Connection**
- Using pastebin.com as ip:port , Instead of noip.com DNS. And Also using multi-ports
- **Plugin**
- Using plugin system to decrease stub's size and lower the AV detection
- **Encryption**
- The communication between server & client is encrypted with AES
- **Spreading**
- Infecting all files and folders on USB drivers
- **Bypass**
- Low AV detection and undetected startup method
- **Lightweight**
- Payload size is about 25 KB
- **Anti Virtual Machines**
- Uninstall itself if the machine is virtual to avoid scanning or analyzing
- **Ransomware**
- Encrypting files on all HHD and USB with .Lime extension
- **XMR Miner**
- High performance Monero CPU miner with user idle\active optimizations
- **DDoS**
- Creating a powerful DDOS attack to make an online service unavailable
- **Crypto Stealer**
- Stealing Cryptocurrency sensitive data
- **Screen-Locker**
- Prevents user from accessing their Windows GUI
- **And more**
- On Connect Auto Task
- Force enable Windows RDP
- Persistence
- File manager
- Passowrds stealer
- Remote desktop

- Bitcoin grabber
- Downloader
- Keylogger

LiteDuke

According to CarbonBlack, LiteDuke is a third stage backdoor. It appears to use the same dropper as PolyglotDuke. Its payload makes use of an AES encrypted SQLite database to store its configuration. LiteDuke supports a large number of individual commands including host information retrieval, file upload and download, and the ability to execute other code. LiteDuke C2 servers appear to be compromised servers, and the malware communicates with them using normal HTTP requests. It attempts to use a realistic User-Agent string to blend in better with normal HTTP traffic. ESET have dubbed it LiteDuke because it uses SQLite to store information such as its configuration.

LockerGoga

According to Trend Micro, LockerGoga is a ransomware that has been used in multiple attacks, most notably against Altran Technologies and Norsk Hydro. It encrypts a range of documents and source code files but certain versions had little to no whitelist that would protect import system files such as the Windows Boot Manager.

Locky

Locky is a high profile ransomware family that first appeared in early 2016 and was observed being active until end of 2017. It encrypts files on the victim system and asks for ransom in order to have back original files. In its first version it added a .locky extension to the encrypted files, and in recent versions it added the .lukitus extension. The ransom amount is defined in BTC and depends on the actor.

Loda

Loda is a previously undocumented AutoIT malware with a variety of capabilities for spying on victims. Proofpoint first observed Loda in September of 2016 and it has since grown in popularity. The name Loda is derived from a directory to which the malware author chose to write keylogger logs. It should be noted that some antivirus products currently detect Loda as “Trojan.Nymeria”,

although the connection is not well-documented.

The tag is: *misp-galaxy:malpedia="Loda"*

Loda is also known as:

Loki Password Stealer (PWS)

"Loki Bot is a commodity malware sold on underground sites which is designed to steal private data from infected machines, and then submit that info to a command and control host via HTTP POST. This private data includes stored passwords, login credential information from Web browsers, and a variety of cryptocurrency wallets." - PhishMe

Loki-Bot employs function hashing to obfuscate the libraries utilized. While not all functions are hashed, a vast majority of them are.

Loki-Bot accepts a single argument/switch of ‘-u’ that simply delays execution (sleeps) for 10 seconds. This is used when Loki-Bot is upgrading itself.

The Mutex generated is the result of MD5 hashing the Machine GUID and trimming to 24-characters. For example: “B7E1C2CC98066B250DDB2123“.

Loki-Bot creates a hidden folder within the %APPDATA% directory whose name is supplied by the 8th thru 13th characters of the Mutex. For example: “%APPDATA%\ C98066\”.

There can be four files within the hidden %APPDATA% directory at any given time: “.exe,” “.lck,” “.hdb” and “.kdb.” They will be named after characters 13 thru 18 of the Mutex. For example: “6B250D.” Below is the explanation of their purpose:

FILE EXTENSION FILE DESCRIPTION .exe A copy of the malware that will execute every time the user account is logged into .lck A lock file created when either decrypting Windows Credentials or Keylogging to prevent resource conflicts .hdb A database of hashes for data that has already been exfiltrated to the C2 server .kdb A database of keylogger data that has yet to be sent to the C2 server

If the user is privileged, Loki-Bot sets up persistence within the registry under HKEY_LOCAL_MACHINE. If not, it sets up persistence under HKEY_CURRENT_USER.

The first packet transmitted by Loki-Bot contains application data.

The second packet transmitted by Loki-Bot contains decrypted Windows credentials.

The third packet transmitted by Loki-Bot is the malware requesting C2 commands from the C2 server. By default, Loki-Bot will send this request out every 10 minutes after the initial packet it sent.

Communications to the C2 server from the compromised host contain information about the user and system including the username, hostname, domain, screen resolution, privilege level, system architecture, and Operating System.

The first WORD of the HTTP Payload represents the Loki-Bot version.

The second WORD of the HTTP Payload is the Payload Type. Below is the table of identified payload types:

BYTE PAYLOAD TYPE 0x26 Stolen Cryptocurrency Wallet 0x27 Stolen Application Data 0x28 Get C2 Commands from C2 Server 0x29 Stolen File 0x2A POS (Point of Sale?) 0x2B Keylogger Data 0x2C Screenshot

The 11th byte of the HTTP Payload begins the Binary ID. This might be useful in tracking campaigns or specific threat actors. This value value is typically “ckav.ru”. If you come across a Binary ID that is different from this, take note!

Loki-Bot encrypts both the URL and the registry key used for persistence using Triple DES encryption.

The Content-Key HTTP Header value is the result of hashing the HTTP Header values that precede it. This is likely used as a protection against researchers who wish to poke and prod at Loki-Bot’s C2 infrastructure.

Loki-Bot can accept the following instructions from the C2 Server:

BYTE INSTRUCTION DESCRIPTION 0x00 Download EXE & Execute 0x01 Download DLL & Load #1 0x02 Download DLL & Load #2 0x08 Delete HDB File 0x09 Start Keylogger 0x0A Mine & Steal Data 0x0E Exit Loki-Bot 0x0F Upgrade Loki-Bot 0x10 Change C2 Polling Frequency 0x11 Delete Executables & Exit

Suricata Signatures RULE SID RULE NAME 2024311 ET TROJAN Loki Bot Cryptocurrency Wallet Exfiltration Detected 2024312 ET TROJAN Loki Bot Application/Credential Data Exfiltration Detected M1 2024313 ET TROJAN Loki Bot Request for C2 Commands Detected M1 2024314 ET TROJAN Loki Bot File Exfiltration Detected 2024315 ET TROJAN Loki Bot Keylogger Data Exfiltration Detected M1 2024316 ET TROJAN Loki Bot Screenshot Exfiltration Detected 2024317 ET TROJAN Loki Bot Application/Credential Data Exfiltration Detected M2 2024318 ET TROJAN Loki Bot Request for C2 Commands Detected M2 2024319 ET TROJAN Loki Bot Keylogger Data Exfiltration Detected M2

L0rdix

L0rdix is a multipurpose .NET remote access tool (RAT) first discovered being sold on underground forums in November 2018. Out of the box, L0rdix supports eight commands, although custom commands can be defined and added. These include:

Download and execute Update Open page (visible) Open page (invisible) Cmd Kill process Upload file HTTP Flood

L0rdix can extract credentials from common web browsers and steal data from crypto wallets and a target's clipboard. Optionally, L0rdix can deploy a cryptominer (XMRig) to its bots.

The tag is: *misp-galaxy:malpedia="L0rdix"*

Lorenz

Tesorion describes Lorenz as a ransomware with design and implementation flaws, leading to impossible decryption with tools provided by the attackers. A free decryptor for 2021 versions was made available via the NoMoreRansom initiative. A new version of the malware was discovered in March 2022, for which again was provided a free decryptor, while the ransomware operators are not able to provide tools to decrypt affected files.

LPEClient

LPEClient is an HTTP(S) downloader that expects two command line parameters: an encrypted string containing two URLs (a primary and a secondary C&C server), and the path on the victim's file system to store the downloaded payload.

It sends detailed information about the victim's environment, like computer name, type and number of processors, computer manufacturer, product name, major and minor Windows versions, architecture, memory information, installed security software and the version of the ntoskrnl.exe from its version-information resource.

LPEClient uses specific 32-bit values to represent its execution state (0x59863F09 when connecting via the WinHTTP interface, 0xA9348B57 via WinINet), or the nature of HTTP requests to the C&C servers (0xF07D6B34 when sending system information, 0xEF8C0D51 when requesting a DLL payload, 0xCB790A25 when reporting the successful loading of the DLL, 0xD7B20A96 when reporting the state of the the DLL execution). As the final step, malware looks for the export CloseEnv and executes it.

Luca Stealer

According to PCRisk, The Luca stealer can extract a variety of information from compromised machines. It targets data related to the following: operating system, device name, CPUs, desktop environment, network interface, user account name, preferred system language, running processes, etc.

This malicious program can steal information from over thirty Chromium-based browsers. From these applications, Luca can obtain Internet cookies, account log-in credentials (usernames/passwords), and credit card numbers. Additionally, the stealer can extract data from password manager and cryptowallet browser extensions compatible with over twenty browsers.

This malware also targets various messaging applications like Telegram, Discord, ICQ, Skype, Element, etc. It likewise aims to acquire information from gaming-related software such as Steam and Uplay (Ubisoft Connect). Furthermore, some versions of Luca can take screenshots and download the files stored on victims' devices.

Lumma Stealer

Lumma Stealer (aka LummaC2 Stealer) is an information stealer written in C language that has been available through a Malware-as-a-Service (MaaS) model on Russian-speaking forums since at least August 2022. It is believed to have been developed by the threat actor "Shamel", who goes by the alias "Lumma". Lumma Stealer primarily targets cryptocurrency wallets and two-factor authentication (2FA) browser extensions, before ultimately stealing sensitive information from the victim's machine. Once the targeted data is obtained, it is exfiltrated to a C2 server via HTTP POST requests using the user agent "TeslaBrowser/5.5"." The stealer also features a non-resident loader that is capable of delivering additional payloads via EXE, DLL, and PowerShell.

The tag is: *misp-galaxy:malpedia="Lumma Stealer"*

Lumma Stealer is also known as:

- LummaC2 Stealer

Lynx

According to Nextron, Lynx ransomware is a sophisticated malware threat that has been active since mid-2024. Lynx has claimed over 20 victims across a range of industries. Once it infiltrates a system, it encrypts critical files, appending a '.lynx' extension, and deletes backup files like shadow copies to hinder recovery. Uniquely, it also sends the ransom note to available printers, adding an unexpected element to its attack strategy. This malware shares similarities with previous INC ransomware, indicating that they bought INC ransomware source code.

Machete

According to ESET, Machete's dropper is a RAR SFX executable. Three py2exe components are dropped: GoogleCrash.exe, Chrome.exe and GoogleUpdate.exe. A single configuration file, jer.dll, is dropped, and it contains base64-encoded text that corresponds to AES-encrypted strings. GoogleCrash.exe is the main component of the malware. It schedules execution of the other two components and creates Windows Task Scheduler tasks to achieve persistence. Regarding the geolocation of victims, Chrome.exe collects data about nearby Wi-Fi networks and sends it to the Mozilla Location Service API. In short, this application provides geolocation coordinates when it's given other sources of data such as Bluetooth beacons, cell towers or Wi-Fi access points. Then the malware takes latitude and longitude coordinates to build a Google Maps URL. The GoogleUpdate.exe component is responsible for communicating with the remote C&C server. The configuration to set the connection is read from the jer.dll file: domain name, username and password. The principal means of communication for Machete is via FTP, although HTTP communication was implemented as a fallback in 2019.

The tag is: *misp-galaxy:malpedia="Machete"*

Machete is also known as:

- El Machete

Maggie

According to DCSO, this malware is written as a Extended Stored Procedure for a MSSQL server. The backdoor has capabilities to bruteforce logins to other MSSQL servers, adding a special hardcoded backdoor user in the case of successfully bruteforcing admin logins.

MagicRAT

According to Talos, MagicRAT is programmed in C++ programming language and uses the Qt Framework by statically linking it to the RAT on 32- and 64-bit versions. The Qt Framework is a programming library for developing graphical user interfaces, of which this RAT has none. Talos thinks that the objective was to increase the complexity of the code, thus making human analysis harder. On the other hand, since there are very few examples (if any) of malware programmed with Qt Framework, this also makes machine learning and heuristic analysis detection less reliable. The RAT uses the Qt classes throughout its entire code. The configuration is dynamically stored in a QSettings class eventually being saved to disk, a typical functionality provided by that class.

MagicRAT provides the operator with a remote shell on the victim's system for arbitrary command execution, along with the ability to rename, move and delete files on the endpoint. The operator can determine the timing for the implant to sleep, change the C2 URLs and delete the implant from the infected system.

Magniber

According to TXOne, The Magniber ransomware was first identified in late 2017 when it was discovered using the Magnitude Exploit Kit to conduct malvertising attacks against users in South Korea. However, it has remained active since then, continually updating its tactics by employing

new obfuscation techniques and methods of evasion. In April 2022, Magniber gained notoriety for disguising itself as a Windows update file to lure victims into installing it. It then began spreading via JavaScript in September 2022.

Makop

BeforeCrypt describes that MAKOP Ransomware first appeared in 2020 as an offshoot of the PHOBOS variant, and that it has infected a number of computers since then. Files encrypted by MAKOP often have the extension ".makop". You may also notice that your desktop wallpaper has changed. MAKOP uses RSA encryption. There are no known free decryption tools capable of decrypting files encrypted by MAKOP.

Maktub

According to PCrisk, Maktub is ransomware distributed via zipped Word documents. Once the file is extracted and opened, Maktub infiltrates the system and encrypts files stored on the victim's computer. Maktub ransomware adds a .NORV, .gyul (or other random) extension to each file encrypted, thus, making it straightforward to determine which files are encrypted.

MASS Logger

MassLogger is a .NET credential stealer. It starts with a launcher that uses simple anti-debugging techniques which can be easily bypassed when identified. This first stage loader eventually XOR-decrypts the second stage assembly which then decrypts, loads and executes the final MassLogger payload.

The tag is: *misp-galaxy:malpedia="MASS Logger"*

Matanbuchus

According to PCrisk, Matanbuchus is a loader-type malicious program offered by its developers as Malware-as-a-Service (MaaS). This piece of software is designed to cause chain infections.

Since it is used as a MaaS, both the malware it infiltrates into systems, and the attack reasons can vary - depending on the cyber criminals operating it. Matanbuchus has been observed being used in attacks against US universities and high schools, as well as a Belgian high-tech organization.

Maze

Maze Ransomware encrypts files and makes them inaccessible while adding a custom extension containing part of the ID of the victim. The ransom note is placed inside a text file and an htm file. There are a few different extensions appended to files which are randomly generated.

Actors are known to exfiltrate the data from the network for further extortion. It spreads mainly using email spam and various exploit kits (Spelevo, Fallout).

The code of Maze ransomware is highly complicated and obfuscated, which helps to evade security solutions using signature-based detections.

The tag is: *misp-galaxy:malpedia="Maze"*

Maze is also known as:

- ChaCha

MedusaLocker

A Windows ransomware that will run certain tasks to prepare the target system for the encryption of files. MedusaLocker avoids executable files, probably to avoid rendering the targeted system unusable for paying the ransom. It uses a combination of AES and RSA-2048, and reportedly appends extensions such as .encrypted, .bomber, .boroff, .breakingbad, .locker16, .newlock, .nlocker, and .skynet.

The tag is: *misp-galaxy:malpedia="MedusaLocker"*

MedusaLocker is also known as:

- AKO Doxware
- AKO Ransomware
- MedusaReborn

Metamorfo

According to BitDefender, Metamorfo is a family of banker Trojans that has been active since mid-2018. It primarily targets Brazilians and is delivered mostly through Office files rigged with macros in spam attachments. Metamorfo is a potent piece of malware, whose primary capability is theft of banking information and other personal data from the user and exfiltration of it to the C2 server.

Midas

This malware written in C# is a variant of the Thanos ransomware family and emerged in October 2021 and is obfuscated using SmartAssembly. In 2022, ThreatLabz analysed a report of Midas ransomware was slowly deployed over a two month period (ZScaler). This ransomware features also its own data leak site as part of its double extortion strategy.

Mimic Ransomware

According to PCrisk, Mimic is a ransomware-type program. Malware within this classification is designed to encrypt data and demand ransoms for decryption. Evidence suggests that Mimic is based on the leaked CONTI ransomware builder. Mimic campaigns have been observed targeting English and Russian speaking users.

The tag is: *misp-galaxy:malpedia="Mimic Ransomware"*

MimiKatz

Varonis summarizes Mimikatz as an open-source application that allows users to view and save authentication credentials like Kerberos tickets. Benjamin Delpy continues to lead Mimikatz developments, so the toolset works with the current release of Windows and includes the most up-to-date attacks.

Attackers commonly use Mimikatz to steal credentials and escalate privileges: in most cases, endpoint protection software and anti-virus systems will detect and delete it. Conversely, pentesters use Mimikatz to detect and exploit vulnerabilities in your networks so you can fix them.

miniBlindingCan

miniBlindingCan is an HTTP(S) orchestrator.

It is a variant of the BlindingCan RAT, having the same command parsing logic, but supporting only a small subset of commands available previously. The main operations are the update of the malware configuration, and the download and execution of additional payloads from the attackers' C&C.

The miniBlindingCan malware was used in Operation DreamJob attacks against aerospace and media companies in Q2-Q3 2022.

The tag is: *misp-galaxy:malpedia="miniBlindingCan"*

miniBlindingCan is also known as:

- AIRDRY.V2
- EventHorizon

MirrorBlast

According to Minerva Labs, MirrorBlast malware is a trojan that is known for attacking users' browsers. It usually pretends to be a legitimate browser add-on however it has now evolved additional capabilities, whereby other malwares are installed simultaneously. Recently, this trojan is thought to have tentative links to TA505 and PYSA groups.

The tag is: *misp-galaxy:malpedia="MirrorBlast"*

Mispadu

According to ESET Research, Mispadu is an ambitious Latin American banking trojan that utilizes McDonald's malvertising and extends its attack surface to web browsers. It is used to target the general public and its main goals are monetary and credential theft. In Brazil, ESET has seen it distributing a malicious Google Chrome extension that attempts to steal credit card data and online banking data, and that compromises the Boleto payment system.

The tag is: *misp-galaxy:malpedia="Mispadu"*

Mispadu is also known as:

- URSA

ModPipe

ModPipe is point-of-sale (POS) malware capable of accessing sensitive information stored in devices running ORACLE MICROS Restaurant Enterprise Series (RES) 3700 POS – a management software suite used by hundreds of thousands of bars, restaurants, hotels and other hospitality establishments worldwide. ModPipe uses modular architecture consisting of basic components and downloadable modules. One of them – named GetMicInfo – contains an algorithm designed to gather database passwords by decrypting them from Windows registry values. Exfiltrated credentials allow ModPipe's operators access to database contents, including various definitions and configuration, status tables and information about POS transactions.

Moisha Ransomware

Moisha is a .NET-based ransomware that employs double extortion techniques to encrypt and exfiltrate data from victims. Upon execution, it creates a global mutex to ensure only one instance of the malware runs on the affected system. It then stops services such as backup and antivirus to avoid interference during the encryption process. Moisha disables real-time protection in Microsoft Defender and removes shadow copies using PowerShell and Vssadmin. It encrypts files on the system using RSA and AES encryption algorithms and places a ransom note in the affected directory. The note instructs victims to contact the attackers via a Moisha ID on TOX Messenger to negotiate the ransom. Additionally, Moisha spreads to other machines on the network and self-deletes using PowerShell command line.

Mount Locker

According to BlackBerry, MountLocker is a Ransomware-as-a-Service (RaaS), active since July 2020 The MountLocker ransomware was updated during early November 2020 to broaden the targeting of file types and evade security software. Victim's files are encrypted using ChaCha20, and file encryption keys are encrypted using RSA-2048. The ransomware appears to be somewhat secure; there are no trivial weaknesses allowing for easy key recovery and decryption of data. MountLocker does however use a cryptographically insecure method for key generation that may

be prone to attack.

The tag is: *misp-galaxy:malpedia="Mount Locker"*

Mount Locker is also known as:

MyDoom

When executed, the worm opens up Windows' Notepad with garbage data in it. When spreading, the infectious email used to distribute the worm copies use variable subjects, bodies and attachment names.

The worm encrypts most of the strings in it’s UPX-packed body with ROT13 method, i.e. the characters are rotated 13 locations to the right in the abecedary, starting from the beginning if the position is beyond the last letter.

Mydoom also performs a Distributed Denial-of-Service attack on www.sco.com. This attack starts on 1st of February.

The worm opens up a backdoor to infected computers. This is done by planting a new SHIMGAPI.DLL file to system32 directory and launching it as a child process of EXPLORER.EXE.

Mydoom is programmed to stop spreading on February 12th.

The tag is: *misp-galaxy:malpedia="MyDoom"*

NedDnLoader

NedDnLoader is an HTTP(S) downloader that uses AES for C&C trafic encryption.

It sends detailed information about the victim's environment, like computer name, user name, type and free disk space of all drives, and a list of currently running processes. It uses three typical parameter names for HTTP POST requests: ned, gl, hl. The usual payload downloaded with NedDnLoader is Torisma.

The internal DLL name of NedDnLoader is usually Dn.dll, Dn64.dll or DnDll.dll. It is deployed either as a standalone payload or within a trojanized MFC application project. It contains specific RTTI symbols like ".?AVCWininet_Protocol@@" or ".?AVCMFC_DLLApp@@".

Nefilim

According to Vitali Kremez and Michael Gillespie, this ransomware shares much code with Nemty 2.5. A difference is removal of the RaaS component, which was switched to email communications for payments. Uses AES-128, which is then protected RSA2048.

The tag is: *misp-galaxy:malpedia="Nefilim"*

NetfilterRootkit

NetfilterRootkit is a WFP application layer enforcement callout driver which is signed by Microsoft via the Windows Hardware Compatibility program. It was first discovered by Karsten Hahn. His team submitted the malware to Microsoft, which allowed Microsoft to start an investigation.

After Karsten Hahn published tweets and an article about the rootkit, Microsoft quickly responded with their own article. Their investigation revealed Chinese gamers as targets of the malware. The rootkit redirects traffic to the threat actor's IP. The threat actor can use the driver to spoof their geo-location to cheat, but it also allows account compromise of targeted players.

While this particular rootkit is not significant anymore, similar rootkits have been created since that are also signed by Microsoft via the Windows Hardware Compatibility program.

The tag is: *misp-galaxy:malpedia="NetfilterRootkit"*

NetSupportManager RAT

Enigma Software notes that NetSupport Manager is a genuine application, which was first released about twenty years ago. The purpose of the NetSupport Manager tool is to enable users to receive remote technical support or provide remote computer assistance. However, cyber crooks have hijacked this useful application and misappropriated it to use it in their harmful campaigns. The name of the modified version of the NetSupport Manager has been labeled the NetSupport Manager RAT.

NET-STAR

According to Unit 42, NET-STAR is a .NET malware suite designed to target Internet Information Services (IIS) web servers. It was named based on the use of the string in the malware's program database (PDB) paths. The suite consists of three distinct web-based backdoors, each serving a specific role in the attack chain while maintaining persistence within the target's IIS environment: A fileless modular backdoor that supports in-memory execution of command-line arguments, arbitrary commands and payloads, a loader for additional Assemblies, and improved version of the Assembly loader that is also equipped with Antimalware Scan Interface (AMSI) and Event Tracing for Windows (ETW) bypass capabilities.

https://www.linkedin.com/pulse/kimsuky-targeting-arms-manufacturer-europe-dmitry-melikov-dquge

NikiTeaR

NikiTeaR is a sophisticated, custom-developed RAT, which is a rewritten variant of the NikiHTTP (aka NikiTea) RAT.

It supports the following commands:

- srun <EXEC> <ARGS>: Executing arbitrary commands with elevated privileges.
- up/down <FILENAME>: Performing remote file operations (upload/download).
- screen: Capturing screenshots for reconnaissance.
- conn <IP_ADDRESS> <PORT>: Establishing a reverse shell
- memload <EXPORT>: Loading additional DLL into memory.
- die <COMMAND>: Terminates the process and remove trace

It is delivered via a multi-staged execution chain, beginning with a Golang-based dropper that executes a loader, a DLL with the internal name MemLoad_V3.dll, capable of loading DLL reflectively.

Its internal DLL name is httptroy_dll.dll.

To resist analysis, the backdoor is heavily obfuscated; it utilizes custom hashing to conceal Windows API calls, and employs a combined Base64+XOR encryption for C&C traffic and internal character strings, which are dynamically reconstructed at runtime.

The tag is: *misp-galaxy:malpedia="NikiTeaR"*

Nitrogen Ransomware

This ransomware has much in common with the LukaLocker ransomware. [1](https://streamscan.ai/en/ressources/analyse-du-rancongiciel-nitrogen/) Analysis of the files reveals strong correlations between the Nitrogen, LukaLocker and Cactus families. These similarities lead us to believe that these ransomware families are administered by the same people, or that the files were developed using a common framework. [2](https://www.glimps.re/en/resource/nitrogen-correlation-with-lukalocker-cactus/)

The tag is: *misp-galaxy:malpedia="Nitrogen Ransomware"*

NjRAT

RedPacket Security describes NJRat as "a remote access trojan (RAT) has capabilities to log keystrokes, access the victim's camera, steal credentials stored in browsers, open a reverse shell, upload/download files, view the victim's desktop, perform process, file, and registry manipulations, and capabilities to let the attacker update, uninstall, restart, close, disconnect the RAT and rename its campaign ID. Through the Command & Control (CnC) server software, the attacker has capabilities to create and configure the malware to spread through USB drives."

It is supposedly popular with actors in the Middle East. Similar to other RATs, many leaked builders may be backdoored.

The tag is: *misp-galaxy:malpedia="NjRAT"*

NjRAT is also known as:

- Bladabindi

- Lime-Worm

Ntospy

Ntospy is a credential stealer leveraging a well-established technique of abusing the Windows Network Provider interface, a method documented as early as 2004 and exemplified by tools like NPPSpy. Posing as a legitimate Network Provider DLL, Ntospy injects itself into the Windows authentication process, hijacking login attempts to harvest user credentials. It achieves this by registering a malicious Network Provider, typically named "credman," which intercepts authentication requests and redirects them to it malicious DLL.

Instead of immediately exfiltrating the stolen data, Ntospy employs a form of local storage, writing the captured credentials in cleartext to files disguised as harmless Microsoft Update packages using

the .msu file extension. These files are often planted in system directories with believable names like "c:/programdata/package cache/windows10.0-kb5009543-x64.msu," further masking their malicious purpose.

Adding to its stealth, Ntospy incorporates obfuscation techniques to evade detection. This includes using seemingly innocuous filenames for its DLL, often mimicking critical system files like "ntoskrnl.dll" to blend in. Some variants even go a step further by encrypting the credential storage file path within the DLL, requiring analysis and decryption to uncover its full functionality.

The tag is: *misp-galaxy:malpedia="Ntospy"*

Nymaim

Nymaim is a trojan downloader. It downloads (and runs) other malware on affected systems and was one of the primary malware families hosted on Avalanche. Nymaim is different in that it displays a localized lockscreen while it downloads additional malware. Nymaim is usually delivered by exploit kits and malvertising.

The tag is: *misp-galaxy:malpedia="Nymaim"*

Nymaim is also known as:

- nymain

Octowave Loader

Octowave Loader is a malware loader used to run other families of malware. This is often made up of an MSI or Inno Setup installer for a legitimate piece of software that has been trojanised to include a number of malicious DLLs which inevitably load and run malicious code often stored within a WAV file that is also delivered to an endpoint. In the wild this has been seen delivered through fake software installers and ClickFix / Fake Captcha campaigns. Families of malware deployed often include information stealers, NetSupport RAT, and potentially bots like Danabot.

Ondritols

According to Symantec, this malware has been deployed against IT services companies in the U.S. and Europe. A multi-stage backdoor, the first stage is a downloader that authenticates to Microsoft Graph API and downloads the second stage payload from OneDrive and executes it. The main payload will download a publicly available file from GitHub. It will then create a folder in OneDrive named deviceId_n_<ip address> for each infected machine and upload a file to OneDrive to signal the attackers the status of a new infection.

Orcus RAT

Orcus has been advertised as a Remote Administration Tool (RAT) since early 2016. It has all the features that would be expected from a RAT and probably more. The long list of the commands is documented on their website. But what separates Orcus from the others is its capability to load custom plugins developed by users, as well as plugins that are readily available from the Orcus repository. In addition to that, users can also execute C# and VB.net code on the remote machine in real-time.

The tag is: *misp-galaxy:malpedia="Orcus RAT"*

Orcus RAT is also known as:

- Schnorchel

Ordinypt

This malware claims to be a ransomware, but it's actually a wiper. After execution, this malware terminates a number of processes such as database processes, likely to allow access to any files that these programs may have held open. Ordinypt will avoid wiping certain files and folders in order to prevent the infected machine from becoming unusable. Affected files are overwritten with null character and receive a random 5 character file extension. Finally, shadow copies are removed and Windows startup repair is disabled to complicate recovery of data from the affected system. The desktop background is changed and a ransom note is dropped for the victim. A C2 check-in occurs to keep track of the file extension used on that specific machine, as well as which BitCoin address was randomly provided for payment to the victim (drawn from a long list stored in the ransomware configuration).

Oski Stealer

Oski is a stealer written in C++ that appeared around November 2019 and is being sold for between 70$ to 100$ on Russian-speaking forums. It collects different types of data (cryptocurrency wallets, saved passwords, files matching an attacker-defined pattern etc) and it exfiltrates it in a zip file uploaded to the attacker's panel.

PandaBanker

According to Arbor, Forcepoint and Proofpoint, Panda is a variant of the well-known Zeus banking trojan(*). Fox IT discovered it in February 2016.

This banking trojan uses the infamous ATS (Automatic Transfer System/Scripts) to automate online bank portal actions.

The baseconfig (c2, crypto material, botnet name, version) is embedded in the malware itself. It then obtains a dynamic config from the c2, with further information about how to grab the webinjects and additional modules, such as vnc, backsocks and grabber.

Panda does have some DGA implemented, but according to Arbor, a bug prevents it from using it.

The tag is: *misp-galaxy:malpedia="PandaBanker"*

PandaBanker is also known as:

- ZeusPanda

Panda Stealer

According to PCrisk, Panda is the name of a malicious program, which is classified as a stealer. It is a new variant of CollectorStealer.

The aim of this malware is to extract and exfiltrate sensitive and personal information from infected devices. Panda primarily targets data relating to cryptocurrency wallets.

This piece of malicious software has been observed being actively distributed via spam campaigns - large-scale operations during which thousands of scam emails are sent. The spam mail proliferating Panda stealer heavily targeted users from the United States, Germany, Japan, and Australia.

The deceptive email letters concerned business-related topics (e.g., fake product quote requests, etc.). Panda stealer is a dangerous program, and as such - its infections must be removed immediately upon detection.

Parite

According to Microsoft, Parite is a family of polymorphic file infectors that targets computers running Microsoft Windows. The virus infects .exe and .scr executable files on the local file system and on writeable network shares. In turn, the infected executable files perform operations that cause other .exe and .scr files to become infected.

PathWiper

According to Cisco Talos, this wiper replaces the contents of artifacts related to the file system with random data generated on the fly. It identifies connected storage media, creates one thread per drive and volume for every path recorded and overwrites artifacts with randomly generated bytes. The wiper also reads multiple file systems attributes from NTFS and overwrites them as well. PathWiper additionally destroys files on disk by overwriting them with randomized bytes.

Peppy RAT

Peppy is a Python-based RAT with the majority of its appearances having similarities or definite overlap with MSIL/Crimson appearances. Peppy communicates to its C&C over HTTP and utilizes SQLite for much of its internal functionality and tracking of exfiltrated files. The primary purpose of Peppy may be the automated exfiltration of potentially interesting files and keylogs. Once Peppy successfully communicates to its C&C, the keylogging and exfiltration of files using configurable search parameters begins. Files are exfiltrated using HTTP POST requests.

The tag is: *misp-galaxy:malpedia="Peppy RAT"*

PetrWrap

The PetrWrap Trojan is written in C and compiled in MS Visual Studio. It carries a sample of the Petya ransomware v3 inside its data section and uses Petya to infect the victim's machine. What's more, PetrWrap implements its own cryptographic routines and modifies the code of Petya in runtime to control its execution. This allows the criminals behind PetrWrap to hide the fact that they are using Petya during infection.

PhantomCore

According to Cyble, PhantomCore is a backdoor utilized by the hacktivist group Head Mare. It has been active since 2023 and is known for consistently targeting Russia. PhantomCore collects the victim's information, including the public IP address, to gain detailed insights into the target before deploying the final-stage payload or executing additional commands on the compromised system. PhantomCore is known to deploy ransomware payloads such as LockBit and Babuk, inflicting significant damage on the victim's systems.

PHOTOFORK

PHOTOFORK is a downloader which is a modified version of GZIPLOADER. It was first detected in February 2023 and was distributed by TA581 along with an unattributed threat activity cluster that facilitated initial access. In this version, the configuration file is no longer encrypted using a simple XOR algorithm with a 64-byte key. Instead, it uses a custom algorithm previously used by the Standard core loader. This algorithm decrypts DLL strings that are needed to resolve handles to the necessary DLLs later on. The strings are decrypted using an algorithm that splits the data into DWORDs and XORs it against a random key. The main objective of PHOTOFORK remains the same as GZIPLOADER, i.e. to deliver an encrypted bot and core DLL loader (forked) that loads the Forked ICEDID bot into memory using a custom PE format.

The tag is: *misp-galaxy:malpedia="PHOTOFORK"*

PHOTOFORK is also known as:

Table 4747. Table References

PHOTOLITE

PHOTOLITE is the lite version of the GZIPLOADER with limited capabilities i.e. for example it does not have any functionality to exfiltrate the host information. This new variant is observed as a follow-on payload in a TA542 Emotet campaign back in November'22. contains a static URL to download a "Bot Pack" file with a static name (botpack.dat) which results in the IcedID Lite DLL Loader, and then delivers the Forked version of IcedID Bot, leaving out the webinjects and

backconnect functionality that would typically be used for banking fraud.

The tag is: *misp-galaxy:malpedia="PHOTOLITE"*

PHOTOLITE is also known as:

PIEHOP

According to Mandiant, PIEHOP is a disruption tool written in Python and packaged with PyInstaller version 2.1+ that has the capability to connect to a user supplied remote MSSQL server for uploading files and issuing remote commands to a RTU. PIEHOP expects its main function to be called via another Python file, supplying either the argument control=True or upload=True. At a minimum, it requires the following arguments: oik, user, and pwd, and if called with control=True, it must also be supplied with iec104.

Pikabot

Introducing Pikabot, an emerging malware family that comprises a downloader/installer, a loader, and a core backdoor component. Despite being in the early stages of development, it already demonstrates advanced techniques in evasion, injection, and anti-analysis. Notably, the loader component incorporates an array of sophisticated anti-debugging and anti-VM measures inspired by the open-source Al-Khaser project, while leveraging steganography to conceal its payload. Additionally, Pikabot utilizes a proprietary C2 framework and supports a diverse range of commands, encompassing host enumeration and advanced secondary payload injection options.

PLAY

According to PCrisk, PLAY is the name of a ransomware-type program. Malware categorized as such operates by encrypting data and demanding ransoms for the decryption.

After we executed a sample of this ransomware on our test machine, it encrypted files and appended their filenames with a ".PLAY" extension. For example, a file titled "1.jpg" appeared as "1.jpg.PLAY", "2.png" as "2.png.PLAY", etc. Once the encryption process was completed, PLAY created a text file named "ReadMe.txt" on the desktop.

The tag is: *misp-galaxy:malpedia="PLAY"*

PLAY is also known as:

- PlayCrypt

PlugX

RSA describes PlugX as a RAT (Remote Access Trojan) malware family that is around since 2008 and is used as a backdoor to control the victim's machine fully. Once the device is infected, an attacker can remotely execute several kinds of commands on the affected system.

Notable features of this malware family are the ability to execute commands on the affected machine to retrieve: machine information capture the screen send keyboard and mouse events keylogging reboot the system manage processes (create, kill and enumerate) manage services (create, start, stop, etc.); and manage Windows registry entries, open a shell, etc.

The malware also logs its events in a text log file.

The tag is: *misp-galaxy:malpedia="PlugX"*

PlugX is also known as:

- Destroy RAT
- Kaba
- Korplug
- RedDelta
- Sogu
- TIGERPLUG

PNGLoad

According to ESET Research, PNGLoad is a second-stage payload deployed by Worok on compromised systems and loaded either by CLRLoad or PowHeartBeat. PNGLoad has capabilities to download and execute additional payloads from a C&C server, which is likely how the attackers have deployed PNGLoad on systems compromised with PowHeartBeat. PNGLoad is a loader that uses bytes from PNG files to create a payload to execute. It is a 64-bit .NET executable - obfuscated with .NET Reactor - that masquerades as legitimate software.

The tag is: *misp-galaxy:malpedia="PNGLoad"*

POISONPLUG

According to FireEye, POISONPLUG is a highly obfuscated modular backdoor with plug-in capabilities. The malware is capable of registry or service persistence, self-removal, plug-in execution, and network connection forwarding. POISONPLUG has been observed using social platforms to host encoded C&C commands.

The tag is: *misp-galaxy:malpedia="POISONPLUG"*

POISONPLUG is also known as:

- Barlaiy

Pony

According to KnowBe4, Pony Stealer is a password stealer that can decrypt or unlock passwords for over 110 different applications including VPN, FTP, email, instant messaging, web browsers and much more. Pony Stealer is very dangerous and once it infects a PC it will turn the device into a botnet, allowing it to use the PCs it infects to infect other PCs.

PoshC2

PoshC2 is a proxy aware C2 framework used to aid penetration testers with red teaming, post-exploitation and lateral movement.

PoshC2 is primarily written in Python3 and follows a modular format to enable users to add their own modules and tools, allowing an extendible and flexible C2 framework. Out-of-the-box PoshC2 comes PowerShell/C# and Python3 implants with payloads written in PowerShell v2 and v4, C++ and C# source code, a variety of executables, DLLs and raw shellcode in addition to a Python3 payload. These enable C2 functionality on a wide range of devices and operating systems, including Windows, *nix and OSX.

The tag is: *misp-galaxy:malpedia="PoshC2"*

PostNapTea

PostNapTea aka SIGNBT is an HTTP(S) RAT that is written as a complex object-oriented project.

In 2022-2023, it was deployed against targets like a newspaper organization, agriculture-related entity or a software vendor. The initial access was usually achieved by exploiting vulnerabilities in

widely-used software in South Korea.

It collects various information about the victim's computer, such as computer name, product name, OS details, system uptime, CPU information, system locale, time zone, network status, and malware configuration.

PostNapTea uses AES for encryption and decryption ot network traffic. There is a constant prefix SIGNBT occuring in its HTTP POST requests. The prefix is concatenated with 2 characters that identify the communication stage: • LG: logging into the C&C server • KE: acknowledging the succesful login to the C&C • FI: sending the status of a failed operation • SR: sending the status of a successful operation • GC: getting the next command

There are five classes that represent command groups: • CCButton: for file manipulation and screen capturing • CCBitmap: for network commands, implementing functionality of Windows commands often abused by attackers, like sc, reg, arp, net, ver, wmic, ping, whoami, netstat, tracert, lookup, ipconfig, systeminfo, and netsh advfirewall. • CCComboBox: for file system management • CCList: for process management • CCBrush: for control of the malware itself

It stores its configuration in JSON format. It resolves the Windows APIs it requires during runtime, via the Fowler–Noll–Vo (FNV) hash function.

Its internal name in the version-information resource is usually ppcsnap.dll or pconsnap.dll, which loosely inspired its code name.

Prestige

According to PCrisk, Prestige is ransomware - malware that prevents victims from accessing (opening) their files by encrypting them. Additionally, Prestige appends the ".enc" extension to filenames and drops the "README" file containing a ransom note. An example of how this

ransomware modifies filenames: it renames "1.jpg" to "1.jpg.enc", "2.png" to "2.png.enc", and so forth.

PromptLock

According to ESET Research, PromptLock is first known AI-powered ransomware. PromptLock leverages Lua scripts generated from hard-coded prompts to enumerate the local filesystem, inspect target files, exfiltrate selected data, and perform encryption. These Lua scripts are cross-platform compatible, functioning on Windows, Linux, and macOS. For its file encryption mechanism, the PromptLock ransomware utilizes the SPECK 128-bit encryption algorithm.

pupy (Windows)

Pupy is an open-source, cross-platform RAT and post-exploitation framework mainly written in python. Pupy can be loaded from various loaders, including PE EXE, reflective DLL, Linux ELF, pure python, powershell and APK. Most of the loaders bundle an embedded python runtime, python library modules in source/compiled/native forms as well as a flexible configuration. They bootstrap a python runtime environment mostly in-memory for the later stages of pupy to run in. Pupy can communicate using various transports, migrate into processes, load remote python code, python packages and python C-extensions from memory.

The tag is: *misp-galaxy:malpedia="pupy (Windows)"*

pupy (Windows) is also known as:

- Patpoopy

PurpleFox

Purple Fox uses msi.dll function, 'MsiInstallProductA', to download and execute its payload. The payload is a .msi file that contains encrypted shellcode including 32-bit and 64-bit versions. once executed the system will be restarted and uses the 'PendingFileRenameOperations' registry to rename it's components.

Upon restart the rootkit capability of Purple Fox is invoked. It creates a suspended svchost process and injects a DLL that will create a driver with the rootkit capability.

The latest version of Purple Fox abuses open-source code to enable it's rootkit components, which

includes hiding and protecting its files and registry entries. It also abuses a file utility software to hide its DLL component, which deters reverse engineering.

PwndLocker

PwndLocker is a ransomware that was observed in late 2019 and is reported to have been used to target businesses and local governments/cities. According to one source, ransom amounts demanded as part of PwndLocker activity range from $175k USD to $650k USD depending on the size of the network. PwndLocker attempts to disable a variety of Windows services so that their data can be encrypted. Various processes will also be targeted, such as web browsers and software related to security, backups, and databases. Shadow copies are cleared by the ransomware, and encryption of files occurs once the system has been prepared in this way. Executable files and those that are likely to be important for the system to continue to function appear to be skipped by the ransomware, and a large number of folders mostly related to Microsoft Windows system files are also ignored. As of March 2020, encrypted files have been observed with the added extensions of .key and .pwnd. Ransom notes are dropped in folders where encrypted files are found and also on the user's desktop.

PyXie

Full-featured Python RAT compiled into an executable.

PyXie RAT functionality includes: * Man-in-the-middle (MITM) Interception * Web-injects * Keylogging * Credential harvesting * Network Scanning * Cookie theft * Clearing logs * Recording video * Running arbitrary payloads * Monitoring USB drives and exfiltrating data * WebDav server * Socks5 proxy * Virtual Network Connection (VNC) * Certificate theft * Inventorying software * Enumerating the domain with Sharphound

The tag is: *misp-galaxy:malpedia="PyXie"*

PyXie is also known as:

- PyXie RAT

QakBot

QBot is a modular information stealer also known as Qakbot or Pinkslipbot. It has been active for years since 2007. It has historically been known as a banking Trojan, meaning that it steals financial data from infected systems, and a loader using C2 servers for payload targeting and download.

The tag is: *misp-galaxy:malpedia="QakBot"*

QakBot is also known as:

- Oakboat
- Pinkslipbot
- Qbot
- Quakbot

QHost

According to F-Secure, this is a network worm with backdoor capabilities, which spreads itself under Win32 systems. The worm was reported in-the-wild in July-August, 2000. The worm itself is a Win32 executable file and about 120K long, written in MS Visual C++.

The tag is: *misp-galaxy:malpedia="QHost"*

QHost is also known as:

- Tolouge

QuanPinLoader

According to ESET Research, this is a loader that has the Mandarin Chinese symbol (yang in the Pinyin transliteration) as an icon in the resources. It also contains the string SampleIMESimplifiedQuanPin.txt, which suggests that it is probably based on the open-source project Sample IME, a TSF-based input method editor demo.

QUICKMUTE

QuickMute is a malware developed using the C/C++ programming language. Functionally provides download, RC4 decryption, and in-memory launch of the payload (waiting for a PE file with the export function "HttpsVictimMain"). To communicate with the management server, a number of protocols are provided, in particular: TCP, UDP, HTTP, HTTPS.

QuiteRAT

QuiteRAT is a simple remote access trojan written with the help of Qt libraries.

After sending preliminary system information to its C&C server, it expects a response containing either a supported command code or an actual Windows command (like systeminfo or ipconfig with parameters) to execute.

It was deployed in a campaign exploiting a ManageEngine ServiceDesk vulnerability (CVE-2022-47966).

The tag is: *misp-galaxy:malpedia="QuiteRAT"*

QuiteRAT is also known as:

- Acres

Racket Downloader

Racket Downloader is an HTTP(S) downloader.

It uses a custom substitution cipher for decryption of its character strings, and RC5 with a 256-bit key for encryption and decryption of network traffic.

It sends an HTTP POST request containing a particular value that inspired its name, like "?product_field=racket" or "prd_fld=racket".

Racket Downloader was deployed against South Korean targets running the Initech INISAFE CrossWeb EX software in Q2 2021 and Q1 2022.

Ragnarok

According to Bleeping Computer, the ransomware is used in targeted attacks against unpatched Citrix servers. It excludes Russian and Chinese targets using the system's Language ID for filtering. It also tries to disable Windows Defender and has a number of UNIX filepath references in its strings. Encryption method is AES using a dynamically generated key, then bundling this key up via RSA.

The tag is: *misp-galaxy:malpedia="Ragnarok"*

Ragnarok is also known as:

Ramnit

According to Check Point, Ramnit is primarily a banking trojan, meaning that its purpose is to steal login credentials for online banking, which cybercriminals can sell or use in future attacks. For this reason, Ramnit primarily targets individuals rather than focusing on particular industries.

Ramnit campaigns have been observed to target organizations in particular industries. For example, a 2019 campaign targeted financial organizations in the United Kingdom, Italy, and Canada.

SNC

Ransomware SNC is a ransomware who encrypts files and asks for a variable amount of Bitcoin before releasing the decryption key to your files. The threat actor asks to be contacted for negotiating the right ransom fee.

The tag is: *misp-galaxy:malpedia="SNC"*

SNC is also known as:

Table 4899. Table References

Rapid Ransom

InfinityGroup notes that Rapid Ransomware, unlike regular Ransomware, stays active on the computer after initially encrypting the systems and also encrypts any new files that are created. It does this by creating auto-runs that are designed to launch the ransomware and display the ransom note every time the infected system is started.

The tag is: *misp-galaxy:malpedia="Rapid Ransom"*

Rapid Ransom is also known as:

Reaver

Reaver is a type of malware discovered by researchers at Palo Alto Networks in November 2017, but its activity dates back to at least late 2016. Researchers identified only ten unique samples of the malware, indicating limited use, and three different variants, noted as versions 1, 2, and 3. The malware is unique as its final payload masquerades as a control panel link (CPL) file. The intended targets of this activity are unknown as of this writing; however, it was used concurrently with the SunOrcal malware and the same C2 infrastructure used by threat actors who primarily target based on the "Five Poisons" - five perceived threats deemed dangerous to, and working against the interests of, the Chinese government.

RecordBreaker

This malware is a successor to Raccoon Stealer (also referred to as Raccoon Stealer 2.0), which is however a full rewrite in C/C++.

RedCap

According to Trend Micro, this backdoor receives valid domain credentials as an argument and uses it to log on to the Exchange Server and use it for data exfiltration purposes. The main function of this stage is to take the stolen password from the argument and send it to the attackers as an attachment in an email. We also observed that the threat actors relay these emails via government Exchange Servers using vaild accounts with stolen passwords.

RedLine Stealer

RedLine Stealer is a malware available on underground forums for sale apparently as a standalone ($100/$150 depending on the version) or also on a subscription basis ($100/month). This malware harvests information from browsers such as saved credentials, autocomplete data, and credit card information. A system inventory is also taken when running on a target machine, to include details such as the username, location data, hardware configuration, and information regarding installed security software. More recent versions of RedLine added the ability to steal cryptocurrency. FTP and IM clients are also apparently targeted by this family, and this malware has the ability to upload and download files, execute commands, and periodically send back information about the infected computer.

The tag is: *misp-galaxy:malpedia="RedLine Stealer"*

RedLine Stealer is also known as:

- RECORDSTEALER

Redosdru

Redosdru is a malware family that primarily acts as a downloader. Upon execution, it may drop downloaded DLLs in the "%ProgramFiles%\AppPatch" directory. The malware modifies the Windows registry to ensure its persistence, adding entries to run automatically at system startup.

ReedBed

ReedBed, identified as a malware proxy backdoor, is suspected to be developed by QAKBOT devs, and was deployed by the threat actor Storm-1811 in campaigns observed during late October and early November 2024. These campaigns are typically initiated with email bombing, a tactic involving mass email distribution, followed by social engineering strategies where the actor impersonates help desk personnel to gain access to victim systems.

Upon execution, ReedBed ensures single-instance operation via the mutex "JhishdiI2Uhsvoc94keiojn7ns19m0do" and hooks critical system APIs (NtCreateUserProcess, RtlExitUserProcess) for defense evasion, process interference, and anti-termination. It reads its Command and Control (C2) configuration, typically from the "Software\TitanPlus" registry key, establishes a persistent SSL/TLS encrypted connection, and transmits an initial system information beacon. Subsequently, ReedBed enters its main operational loop, acting as a versatile network proxy based on C2 commands; this includes initiating outgoing TCP connections, relaying data bi-directionally, and establishing reverse SOCKS5 (with authentication) or direct TCP port mapping services via locally opened listening ports. If commanded or upon connection failure, it transitions into a restart/wait cycle guided by registry values, leveraging its hooked exit function to hinder termination before attempting to reconnect to the C2.

Regin

Regin is a sophisticated malware and hacking toolkit attributed to United States' National Security Agency (NSA) for government spying operations. It was first publicly revealed by Kaspersky Lab, Symantec, and The Intercept in November 2014. Regin malware targeted victims in a range of industries, telecom, government, and financial institutions. It was engineered to be modular and over time dozens of modules have been found and attributed to this family. Symantec observed around 100 infections in 10 different countries across a variety of organisations including private companies, government entities, and research institutes.

Remcos

Remcos (acronym of Remote Control & Surveillance Software) is a commercial Remote Access Tool to remotely control computers.

Remcos is advertised as legitimate software which can be used for surveillance and penetration testing purposes, but has been used in numerous hacking campaigns. Remcos, once installed, opens a backdoor on the computer, granting full access to the remote user. Remcos is developed by the cybersecurity company BreakingSecurity.

Remexi

Remexi is a highly advanced and stealthy malware discovered in recent times. It employs sophisticated evasion techniques to infiltrate target systems and networks undetected. This malware utilizes various propagation vectors, including exploit kits, social engineering tactics, and compromised websites. Once inside a system, Remexi establishes persistence through rootkit capabilities and leverages coAmmand-and-control infrastructure to receive and execute malicious commands. It possesses keylogging and data exfiltration capabilities, enabling it to steal sensitive information such as login credentials and financial data. Additionally, Remexi can download and execute additional payloads, making it adaptable and capable of evolving its malicious activities over time.

Retefe (Windows)

Retefe is a Windows Banking Trojan that can also download and install additional malware onto the system using Windows PowerShell. It's primary functionality is to assist the attacker with stealing credentials for online banking websites. It is typically targeted against Swiss banks. The malware binary itself is primarily a dropper component for a Javascript file which builds a VBA file which in turn loads multiple tools onto the host including: 7zip and TOR. The VBA installs a new root certificate and then forwards all traffic via TOR to the attacker controlled host in order to

effectively MITM TLS traffic.

The tag is: *misp-galaxy:malpedia="Retefe (Windows)"*

Retefe (Windows) is also known as:

- Tsukuba
- Werdlod

Revenant

According to its author, Revenant is a 3rd party agent for Havoc written in C, and based on Talon. This implant is meant to expand on the Talon implant by implementing covert methods of execution, robust capabilities, and more customization.

The tag is: *misp-galaxy:malpedia="Revenant"*

Revenant is also known as:

REvil (Windows)

REvil Beta MD5: bed6fc04aeb785815744706239a1f243 SHA1: 3d0649b5f76dbbff9f86b926afbd18ae028946bf SHA256: 3641b09bf6eae22579d4fd5aae420476a134f5948966944189a70afd8032cb45 * Privilege escalation via CVE-2018-8453 (64-bit only) * Rerun with RunAs to elevate privileges * Implements a requirement that if "exp" is set, privilege escalation must be successful for full execution to occur * Implements target whitelisting using GetKetboardLayoutList * Contains debug console logging functionality * Defines the REvil registry root key as SOFTWARE\!test * Includes two variable placeholders in the ransom note: UID & KEY * Terminates processes specified in the "prc" configuration key prior to encryption * Deletes shadow copies and disables recovery * Wipes contents of folders specified in the "wfld" configuration key prior to encryption * Encrypts all non-whitelisted files on fixed drives * Encrypts all non-whitelisted files on network mapped drives if it is running with System-level privileges or can impersonate the security context of explorer.exe * Partially implements a background image setting to display a basic "Image text" message * Sends encrypted system data to a C2 domain via an HTTPS POST request (URI path building is not implemented.)

```
REvil 1.00
MD5: 65aa793c000762174b2f86077bdafaea
SHA1: 95a21e764ad0c98ea3d034d293aee5511e7c8457
SHA256: f0c60f62ef9ffc044d0b4aeb8cc26b971236f24a2611cb1be09ff4845c3841bc
* Adds 32-bit implementation of CVE-2018-8453 exploit
* Removes console debug logging
* Changes the REvil registry root key to SOFTWARE\recfg
* Removes the System/Impersonation success requirement for encrypting network mapped
```

```
drives
* Adds a "wipe" key to the configuration for optional folder wiping
* Fully implements the background image setting and leverages values defined in the
"img" configuration key
* Adds an EXT variable placeholder to the ransom note to support UID, KEY, and EXT
* Implements URI path building so encrypted system data is sent to a C2 pseudo-random
URL
* Fixes the function that returns the victim's username so the correct value is placed
in the stats JSON data
```

REvil 1.01 MD5: 2abff29b4d87f30f011874b6e98959e9 SHA1: 9d1b61b1cba411ee6d4664ba2561fa59cdb0732c SHA256: a88e2857a2f3922b44247316642f08ba8665185297e3cd958bbd22a83f380feb * Removes the exp/privilege escalation requirement for full execution and encrypts data regardless of privilege level * Makes encryption of network mapped drives optional by adding the "-nolan" argument

```
REvil 1.02
MD5: 4af953b20f3a1f165e7cf31d6156c035
SHA1: b859de5ffcb90e4ca8e304d81a4f81e8785bb299
SHA256: 89d80016ff4c6600e8dd8cfad1fa6912af4d21c5457b4e9866d1796939b48dc4
* Enhances whitelisting validation by adding inspection of GetUserDefaultUILanguage
and GetSystemDefaultUILanguage
* Partially implements "lock file" logic by generating a lock filename based on the
first four bytes of the Base64-decoded pk key, appending a .lock file extension, and
adding the filename to the list of whitelisted files in the REvil configuration (It
does not appear that this value is referenced after it is created and stored in
memory. There is no evidence that a lock file is dropped to disk.)
* Enhances folder whitelisting logic that take special considerations if the folder is
associated with "program files" directories
* Hard-codes whitelisting of all direct content within the Program Files or Program
Files x86 directories
* Hard-codes whitelisting of "sql" subfolders within program files
* Encrypts program files sub-folders that does not contain "sql" in the path
* Compares other folders to the list of whitelisted folders specified in the REvil
configuration to determine if they are whitelisted
* Encodes stored strings used for URI building within the binary and decodes them in
memory right before use
* Introduces a REvil registry root key "sub_key" registry value containing the
attacker's public key
```

REvil 1.03 MD5: 3cae02306a95564b1fff4ea45a7dfc00 SHA1: 0ce2cae5287a64138d273007b34933362901783d SHA256: 78fa32f179224c46ae81252c841e75ee4e80b57e6b026d0a05bb07d34ec37bbf * Removes lock file logic that was partially implemented in 1.02 * Leverages WMI to continuously monitor for and kill newly launched processes whose names are listed in the prc configuration key (Previous versions performed this action once.) * Encodes stored shellcode * Adds the -path argument: * Does not wipe folders (even if wipe == true) * Does not set desktop background * Does not contact the C2 server (even if net == true) * Encrypts files in the specified folder and drops the ransom note * Changes the

REvil registry root key to SOFTWARE\QtProject\OrganizationDefaults * Changes registry key values from -→ to: * sub_key -→ pvg * pk_key -→ sxsP * sk_key -→ BDDC8 * 0_key -→ f7gVD7 * rnd_ext -→ Xu7Nnkd * stat -→ sMMnxpgk

```
REvil 1.04
MD5: 6e3efb83299d800edf1624ecbc0665e7
SHA1: 0bd22f204c5373f1a22d9a02c59f69f354a2cc0d
SHA256: 2ca64feaaf5ab6cf96677fbc2bc0e1995b3bc93472d7af884139aa757240e3f6
* Leverages PowerShell and WMI to delete shadow copies if the victim's operating
system is newer than Windows XP (For Windows XP or older, it uses the original command
that was executed in all previous REvil versions.)
* Removes the folder wipe capability
* Changes the REvil registry root key to SOFTWARE\GitForWindows
* Changes registry key values from --> to:
  * pvg --> QPM
  * sxsP --> cMtS
  * BDDC8 --> WGg7j
  * f7gVD7 --> zbhs8h
  * Xu7Nnkd --> H85TP10
  * sMMnxpgk --> GCZg2PXD
```

REvil v1.05 MD5: cfefcc2edc5c54c74b76e7d1d29e69b2 SHA1: 7423c57db390def08154b77e2b5e043d92d320c7 SHA256: e430479d1ca03a1bc5414e28f6cdbb301939c4c95547492cdbe27b0a123344ea * Add new 'arn' configuration key that contains a boolean true/false value that controls whether or not to implement persistence. * Implements persistence functionality via registry Run key. Data for value is set to the full path and filename of the currently running executable. The executable is never moved into any 'working directory' such as %AppData% or %TEMP% as part of the persistence setup. The Reg Value used is the hardcoded value of 'lNOWZyAWVv' : * SOFTWARE\Microsoft\Windows\CurrentVersion\Run\lNOWZyAWVv * Before exiting, REvil sets up its malicious executable to be deleted upon reboot by issuing a call to MoveFileExW and setting the destination to NULL and the flags to 4 (MOVEFILE_DELAY_UNTIL_REBOOT). This breaks persistence however as the target executable specified in the Run key will no longer exist once this is done. * Changes registry key values from -→ to: * QPM -→ tgE * cMtS -→ 8K09 * WGg7j -→ xMtNc * zbhs8h -→ CTgE4a * H85TP10 -→ oE5bZg0 * GCZg2PXD -→ DC408Qp4

```
REvil v1.06
MD5: 65ff37973426c09b9ff95f354e62959e
SHA1: b53bc09cfbd292af7b3609734a99d101bd24d77e
SHA256: 0e37d9d0a7441a98119eb1361a0605042c4db0e8369b54ba26e6ba08d9b62f1e
* Updated string decoding function to break existing yara rules. Likely the result of
the blog posted by us.
* Modified handling of network file encryption. Now explicitly passes every possible
"Scope" constant to the WNetOpenEnum function when looking for files to encrypt. It
also changed the 'Resource Type" from RESOURCETYPE_DISK to RESOURCETYPE_ANY which will
now include things like mapped printers.
* Persistence registry value changed from 'lNOWZyAWVv' to 'sNpEShi30R'
* Changes registry key values from --> to:
```

```
  * tgE --> 73g
  * 8K09 --> vTGj
  * xMtNc --> Q7PZe
  * CTgE4a --> BuCrIp
  * oE5bZg0 --> lcZd7OY
  * DC408Qp4 --> sLF86MWC
```

REvil v1.07 MD5: ea4cae3d6d8150215a4d90593a4c30f2 SHA1: 8dcbcbefaedf5675b170af3fd44db93ad864894e SHA256: 6a2bd52a5d68a7250d1de481dcce91a32f54824c1c540f0a040d05f757220cd3 TBD

Rhadamanthys

According to PCrisk, Rhadamanthys is a stealer-type malware, and as its name implies - it is designed to extract data from infected machines.

At the time of writing, this malware is spread through malicious websites mirroring those of genuine software such as AnyDesk, Zoom, Notepad++, and others. Rhadamanthys is downloaded alongside the real program, thus diminishing immediate user suspicion. These sites were promoted through Google ads, which superseded the legitimate search results on the Google search engine.

The tag is: *misp-galaxy:malpedia="Rhadamanthys"*

RiseLoader

RiseLoader is a new malware loader family first observed in October 2024. It uses a custom TCP-based binary network protocol similar to, but distinct from, that used by the PrivateLoader and

RisePro malware families. RiseLoader often drops other malware families, such as Vidar, Lumma Stealer, and XMRig, as secondary payloads. It collects information about installed applications and browser extensions, likely related to cryptocurrency.

Key technical characteristics of RiseLoader include:

Anti-analysis Techniques: Samples are often packed with VMProtect and obfuscate strings related to malware analysis and debugging tools.

Behavioural Analysis: Creates a mutex with a hardcoded prefix and randomly generated suffixes. Communicates with a C2 server over TCP using a custom protocol involving specific message types for tasks such as transferring system information, receiving payloads, and confirming execution. Downloads and executes payloads from URLs provided by the C2 server. Creates registry keys as infection markers.

Network Communication: Uses a custom TCP-based protocol with message types like SEND_VICTIM_INFO, SYS_INFO, PAYLOADS, KEEPALIVE, and others. Data is XOR encoded using keys exchanged via a SET_XORKEYS message. The protocol includes a three-way handshake and mechanisms for re-establishing connections.

Similarities to RisePro/PrivateLoader: Shares similar network communication protocols and message structures with RisePro and PrivateLoader suggesting a potential link between their developers, though RiseLoader's protocol appears simplified. It currently lacks RisePro/PrivateLoader's information-stealing features but may be under development.

ROLLCOAST

ROLLCOAST is a ransomware program that encrypts files on logical drives attached to a system. ROLLCOAST is a Dynamic Linked Library (DLL) with no named exports. When observed by Mandiant it uniquely had only one ordinal export 0x01. This suggested the sample was designed to

avoid detection and be invoked within memory, possibly through BEACON provided to affiliates. Incident responders working on similar intrusions should capture memory for analysis.

The tag is: *misp-galaxy:malpedia="ROLLCOAST"*

ROLLCOAST is also known as:

- Arcane
- S4bb47h
- Sabbath

Rook

According to PCrisk, Rook is ransomware (an updated variant of Babuk) that prevents victims from accessing/opening files by encrypting them. It also modifies filenames and creates a text file/ransom note ("HowToRestoreYourFiles.txt"). Rook renames files by appending the ".Rook" extension. For example, it renames "1.jpg" to "1.jpg.Rook", "2.jpg" to "2.jpg.Rook".

Running RAT

NJCCIC characterizes RunningRAT as a remote access trojan (RAT) that operates using two DLL files. When the trojan is loaded onto a system, it executes the first DLL. This is used to disable anti-malware solutions, unpack and execute the main RAT DLL, and gain persistence. The trojan installs a Windows batch file dx.bat that attempts to kill the daumcleaner.exe task, a Korean security program. The file then attempts to remove itself. Once the second DLL is loaded into memory, the first DLL overwrites the IP address for the control server to change the address the trojan communicates with. The second DLL gathers information about the victim's system, including its operating system and driver and processor information. The RAT can log user keystrokes, copy the clipboard, delete files, compress files, clear event logs, shut down the machine, and more. The second DLL also uses several anti-bugging techniques.

The tag is: *misp-galaxy:malpedia="Running RAT"*

Ryuk

Ryuk is a ransomware which encrypts its victim's files and asks for a ransom via bitcoin to release the original files. It is has been observed being used to attack companies or professional environments. Cybersecurity experts figured out that Ryuk and Hermes ransomware shares pieces of codes. Hermes is commodity ransomware that has been observed for sale on dark-net forums and used by multiple threat actors.

SADBRIDGE

According to Elastic, SADBRIDGE is a malware loader packaged as an MSI executable for delivery and it uses DLL side-loading with various injection techniques to execute malicious payloads. SADBRIDGE abuses legitimate applications such as x64dbg.exe and MonitoringHost.exe to load malicious DLLs like x64bridge.dll and HealthServiceRuntime.dll, which leads to subsequent stages and shellcodes.

Sagerunex

According to Symantec, Sagerunex is a backdoor that is fairly resilient and implements multiple forms of communication with its command-and-control (C&C) server. Its logs are encrypted and the encryption algorithm used is AES256-CBC with 8192 rounds of SHA256 for key derivation based on a hardcoded key. It supports multiple modes methods for communicating via HTTP (proxy-aware).

Sality

F-Secure states that the Sality virus family has been circulating in the wild as early as 2003. Over the years, the malware has been developed and improved with the addition of new features, such as rootkit or backdoor functionality, and so on, keeping it an active and relevant threat despite the relative age of the malware.

Modern Sality variants also have the ability to communicate over a peer-to-peer (P2P) network, allowing an attacker to control a botnet of Sality-infected machines. The combined resources of the Sality botnet may also be used by its controller(s) to perform other malicious actions, such as attacking routers.

Infection Sality viruses typically infect executable files on local, shared and removable drives. In earlier variants, the Sality virus simply added its own malicious code to the end of the infected (or host) file, a technique known as prepending. The viral code that Sality inserts is polymorphic, a form of complex code that is intended to make analysis more difficult.

Earlier Sality variants were regarded as technically sophisticated in that they use an Entry Point Obscuration (EPO) technique to hide their presence on the system. This technique means that the virus inserts a command somewhere in the middle of an infected file's code, so that when the system is reading the file to execute it and comes to the command, it forces the system to 'jump' to the malware's code and execute that instead. This technique was used to make discovery and disinfection of the malicious code harder.

Payload Once installed on the computer system, Sality viruses usually also execute a malicious payload. The specific actions performed depend on the specific variant in question, but generally Sality viruses will attempt to terminate processes, particularly those related to security programs. The virus may also attempt to open connections to remote sites, download and run additional malicious files, and steal data from the infected machine.

The tag is: *misp-galaxy:malpedia="Sality"*

Sality is also known as:

Scavenger

Scavenger is a stealthy, two-stage malware family first observed in July 2025 following a targeted supply chain attack on the NPM ecosystem. The infection began with a phishing campaign that leveraged a typo-squatted domain (npnjs.com) to impersonate the legitimate NPM login page. The adversaries abused NPM's web-based login flow—akin to device code phishing—to trick a package maintainer into generating an automation access token, which does not expire and can bypass 2FA under certain configurations.

With the stolen credentials, the attackers injected malicious payloads into several trusted NPM packages, including eslint-config-prettier, by modifying their install scripts to execute a DLL loader. This first-stage loader, compiled in Visual Studio, performs anti-VM checks, dynamic API resolution using CRC32 hashing, indirect syscalls to bypass EDR, and string decryption routines. If the environment passes these checks, it executes a second-stage infostealer that targets browser data—particularly from Chromium—such as extension state, cached content, and visited URLs.

The malware communicates with its command and control infrastructure using libcurl and XXTEA-encrypted payloads over HTTP(S), implementing challenge-response integrity checks during session initialization. Development artifacts like a leftover PDB path and operational overlaps have linked Scavenger to other campaigns, including one involving an infected BeamNG game binary, further suggesting a broader and evolving threat infrastructure.

The tag is: *misp-galaxy:malpedia="Scavenger"*

Scavenger is also known as:

- SCVNGR

- scavenger
- scvngr

ScoringMathTea

According to ESET Research, ScoringMathTea is a RAT that offers the attackers full control over the compromised machine. Its first appearance dates to late 2022, when its dropper was uploaded to VirusTotal. Soon after, it was seen in the wild, and since then in multiple attacks attributed to Lazarus' Operation DreamJob campaigns, which makes it the attacker's payload of choice for already three years. It uses compromised servers for C&C communication, with the server part usually stored under the WordPress folder containing design templates or plugins.

SecondHandTea

SecondHandTea is a full-featured Remote Access Trojan (RAT), closely related to BackbitingTea, the flagship backdoor used in the DangerousPassword campaigns (also known as SnatchCrypto).

Both malware families appear to share a common codebase and are compiled within the same build environment.

While they share most core functionality and supported commands, SecondHandTea differs from BackbitingTea variants in several technical aspects:

- Configuration file paths
- Network libraries: OpenSSL 1.1.0f vs. wolfSSL or Winsock TCP/IP
- Encryption algorithms: AES-256 vs. RC4
- Compression methods: LZ4 vs. ZIP

These differences suggest active development and customization efforts tailored to specific operational needs.

The malware's name was inferred from its internal filename: SecondT_x64.exe.

Between H2 2022 and Q1 2023, SecondHandTea was observed in targeted attacks against entities involved in cryptotrading and blockchain technology, indicating a continued focus on financially motivated cyber operations.

The tag is: *misp-galaxy:malpedia="SecondHandTea"*

ServHelper

ServHelper is written in Delphi and according to ProofPoint best classified as a backdoor.

ProofPoint noticed two distinct variant - "tunnel" and "downloader" (citation): "The 'tunnel' variant has more features and focuses on setting up reverse SSH tunnels to allow the threat actor to access the infected host via Remote Desktop Protocol (RDP). Once ServHelper establishes remote desktop access, the malware contains functionality for the threat actor to 'hijack' legitimate user accounts or their web browser profiles and use them as they see fit. The 'downloader' variant is stripped of the tunneling and hijacking functionality and is used as a basic downloader."

SharpStage

The SharpStage backdoor is a .NET malware with backdoor capabilities. Its name is a derivative of the main activity class called “Stage_One”. SharpStage can take screenshots, run arbitrary commands and downloads additional payloads. It exfiltrates data from the infected machine to a dropbox account by implementing a dropbox client in its code. SharpStage was seen used by the Molerats group in targeted attacks in the middle east.

The tag is: *misp-galaxy:malpedia="SharpStage"*

SharpStage is also known as:

ShellLocker

PCRIsk states that ShellLocker is a ransomware-type virus developed using .NET framework. It was first discovered by Jakub Kroustek and is virtually identical to another ransomware virus called Exotic.

Following infiltration, this virus encrypts stored data (video, audio, etc.) and renames encrypted files using the "[random_characters].L0cked" pattern (e.g., "sample.jpg" might be renamed to "gd&=AA0fgoi.L0cked"). Following successful encryption, ShellLocker opens a pop-up window containing ransom-demand message.

ShortLeash (Windows)

According to STRIKE, ShortLeash is a custom backdoor used to create an ORB network. It generates unique, self-signed TLS certificates with spoofed metadata for each node. Analysis of these certificates revealed over 1000 active nodes globally and victimology supports attribution to China-Nexus APTs.

The tag is: *misp-galaxy:malpedia="ShortLeash (Windows)"*

Silence

According to PCrisk, Truebot, also known as Silence.Downloader, is a malicious program that has botnet and loader/injector capabilities. This malware can add victims' devices to a botnet and cause chain system infections (i.e., download/install additional malicious programs/components).

There is significant variation in Truebot’s infection chains and distribution. It is likely that the attackers using this malicious software will continue to make such changes.

The tag is: *misp-galaxy:malpedia="Silence"*

Sliver

According to VK9 Seecurity, Sliver is a Command and Control (C2) system made for penetration testers, red teams, and advanced persistent threats. It generates implants (slivers) that can run on virtually every architecture out there, and securely manage these connections through a central server. Sliver supports multiple callback protocols including DNS, TCP, and HTTP(S) to make egress simple, even when those pesky blue teams block your domains. You can even have multiple operators (players) simultaneously commanding your sliver army.

SlothfulMedia

According to MITRE, SLOTHFULMEDIA is a remote access Trojan written in C++ that has been used by an unidentified "sophisticated cyber actor" since at least January 2017. It has been used to target government organizations, defense contractors, universities, and energy companies in Russia, India, Kazakhstan, Kyrgyzstan, Malaysia, Ukraine, and Eastern Europe.

SMAUG

According to PCrisk, Smaug ransomware is available for download on the dark web: it is for sale as Ransomware as a Service (RaaS). Therefore, cyber criminals who purchase it can perform ransomware attacks without having to develop malware of this type. Smaug is designed to encrypt files, rename them and create a ransom message.

The tag is: *misp-galaxy:malpedia="SMAUG"*

SmokeLoader

The SmokeLoader family is a generic backdoor with a range of capabilities which depend on the modules included in any given build of the malware. The malware is delivered in a variety of ways and is broadly associated with criminal activity. The malware frequently tries to hide its C2 activity by generating requests to legitimate sites such as microsoft.com, bing.com, adobe.com, and others. Typically the actual Download returns an HTTP 404 but still contains data in the Response Body.

Snake

Snake Ransomware is a Golang ransomware reportedly containing obfuscation not typically seen in Golang ransomware. This malware will remove shadow copies and kill processes related to SCADA/ICS devices, virtual machines, remote management tools, network management software, and others. After this, encryption of files on the device commences, while skipping Windows system folders and various system files. A random 5 character string is appended to encrypted files. According to Bleeping Computer, this ransomware takes an especially long time to encrypt files on a targeted machine. This ransomware is reported to target an entire network, rather than individual workstations.

The tag is: *misp-galaxy:malpedia="Snake"*

Snake is also known as:

- EKANS
- SNAKEHOSE

Snatch

Snatch is a ransomware which infects victims by rebooting the PC into Safe Mode. Most of the existing security protections do not run in Safe Mode so that it the malware can act without expected countermeasures and it can encrypt as many files as it finds. It uses common packers such as UPX to hide its payload.

The tag is: *misp-galaxy:malpedia="Snatch"*

Snatch is also known as:

Socks5 Systemz

The Socks5 Systemz malware is a proxy botnet distributed via the PrivateLoader and Amadey loaders. Active since at least 2016, this botnet infects devices to use them as proxies for malicious activities, offering access for prices ranging from $1 to $140 per day in cryptocurrency. It employs a domain generation algorithm (DGA) to evade detection and enhance its resilience. Persistence is

maintained through a Windows service named ContentDWSvc, with the malware injected into memory via a file called previewer.exe. To date, it has compromised approximately 10,000 devices globally, excluding Russia.

solarmarker

Unit 42 notes that they identified a new version of SolarMarker, a malware family known for its infostealing and backdoor capabilities, mainly delivered through search engine optimization (SEO) manipulation to convince users to download malicious documents.

Some of SolarMarker's capabilities include the exfiltration of auto-fill data, saved passwords and saved credit card information from victims' web browsers. Besides capabilities typical for infostealers, SolarMarker has additional capabilities such as file transfer and execution of commands received from a C2 server.

The malware invests significant effort into defense evasion, which consists of techniques like signed files, huge files, impersonation of legitimate software installations and obfuscated PowerShell scripts.

The tag is: *misp-galaxy:malpedia="solarmarker"*

solarmarker is also known as:

- Jupyter
- Polazert
- Yellow Cockatoo

SPACESHIP

SPACESHIP searches for files with a specified set of file extensions and copies them to a removable drive. FireEye believes that SHIPSHAPE is used to copy SPACESHIP to a removable drive, which could be used to infect another victim computer, including an air-gapped computer. SPACESHIP is then used to steal documents from the air-gapped system, copying them to a removable drive inserted into the SPACESHIP-infected system

SpyEye

SpyEye is a malware targeting both Microsoft Windows browsers and Apple iOS Safari. Originated in Russia, it was available in dark forums for $500+ claiming to be the "The Next Zeus Malware". It performed many functionalities typical from bankers trojan such as keyloggers, auto-fill credit card modules, email backups, config files (encrypted), http access, Pop3 grabbers and FTP grabbers. SpyEye allowed hackers to steal money from online bank accounts and initiate transactions even while valid users are logged into their bank account.

Squirrelwaffle

According to Sophos, Squirrelwaffle is a malware loader that is distributed as a malicious Office document in spam campaigns. It provides attackers with an initial foothold in a victim's environment and a channel to deliver and infect systems with other malware. When a recipient opens a Squirrelwaffle-infected document and enables macros, a visual basic script typically downloads and executes malicious files and scripts, giving further control of the computer to an attacker. Squirrelwaffle operators also use DocuSign to try and trick the user into enabling macros in Office documents.

SquirtDanger

According to PaloAlto, SquirtDanger is a commodity botnet malware family that comes equipped with a number of characteristics and capabilities. The malware is written in C# (C Sharp) and has multiple layers of embedded code. Once run on the system, it will persist via a scheduled task that is set to run every minute. SquirtDanger uses raw TCP connections to a remote command and control (C2) server for network communications.

The tag is: *misp-galaxy:malpedia="SquirtDanger"*

SSLoad

SSLoad is a Rust-based downloader that first emerged in January 2024 and is used to deliver secondary payloads. Early versions of the malware used a first-stage DLL that connected to a Telegram channel named 'SSLoad' to retrieve another URL. It then downloaded a compressed PE file using a hardcoded User-Agent (SSLoad/1.x) and Content-Type over HTTP. The downloaded file was then decompressed and executed directly in memory. The malware has since undergone several updates, including changes to the command-and-control (C2) communication and the supporting executables that load the malware. Recent versions of the malware bypass the first-stage DLL by loading SSLoad directly onto the victim's machine.

Statc

This malicious software gains access to a victim's data by appearing like an authentic Google advertisement. Once the victim clicks on the advertisement, their operating system is infected with malicious code that steals sensitive data like credentials from web browsers, credit card information, and cryptocurrency wallet details. Unauthorized access to a victim's computer system can have enormous personal and professional repercussions. Victims become easy targets for identity theft, cryptojacking, and other forms of malware attacks. At the enterprise level, a Statc Stealer breach can result in financial loss, reputational damage, legal liabilities, and regulatory penalties.

Stealc

Stealc is an information stealer advertised by its presumed developer Plymouth on Russian-speaking underground forums and sold as a Malware-as-a-Service since January 9, 2023. According to Plymouth's statement, stealc is a non-resident stealer with flexible data collection settings and its development is relied on other prominent stealers: Vidar, Raccoon, Mars and Redline.

Stealc is written in C and uses WinAPI functions. It mainly targets date from web browsers, extensions and Desktop application of cryptocurrency wallets, and from other applications (messengers, email clients, etc.). The malware downloads 7 legitimate third-party DLLs to collect sensitive data from web browsers, including sqlite3.dll, nss3.dll, vcruntime140.dll, mozglue.dll, freebl3.dll, softokn3.dll and msvcp140.dll. It then exfiltrates the collected information file by file to its C2 server using HTTP POST requests.

Stealerium

According to SecurityScorecard, Stealerium is an open-source stealer available on GitHub. The malware steals information from browsers, cryptocurrency wallets, and applications such as Discord, Pidgin, Outlook, Telegram, Skype, Element, Signal, Tox, Steam, Minecraft, and VPN clients. The binary also gathers data about the infected host, such as the running processes, Desktop and webcam screenshots, Wi-Fi networks, the Windows product key, and the public and private IP

address. The stealer employs multiple anti-analysis techniques, such as detecting virtual machines, sandboxes, and malware analysis tools and checking if the process is being debugged. The malware also embedded a keylogger module and a clipper module that replaces cryptocurrency wallet addresses with the threat actor's addresses if the victim makes a transaction. The stolen information is sent to a Discord channel using a Discord Webhook.

StealthWorker Go

According to Fortinet, StealthWorker is a brute-force malware that has been linked to a compromised e-commerce website with an embedded skimmer that steals personal information and payment details. Before hackers can embed a skimmer, however, the first requirement is for hackers to gain access to their target's backend. Hacker's commonly take advantage of vulnerabilities in the Content Management System (CMS) or its plugins to gain entry into the target's system. Another, simpler option is to use brute force attacks. Though quite slow, this method is still effective against administrators using weak or commonly used passwords.

StormKittyRAT

According to unpac.me, StormKitty is a Remote Access Trojan (RAT), written in C#, primarily designed to perform extensive system reconnaissance and data collection. It leverages Windows Management Instrumentation for execution and conducts a thorough discovery of system information, including querying the registry, identifying system owners and users, and discovering network configurations. StormKitty is also capable of collecting data from information repositories and performing file and directory discovery. For defense evasion, it employs techniques such as

obfuscating files or information and checks for virtualization or sandbox environments to avoid detection. These capabilities enable StormKitty to maintain persistence and gather sensitive information from compromised systems.

StrelaStealer

According to PCRisk, StrelaStealer seeks to extract email account log-in credentials. At the time of writing, this program targets Microsoft Outlook and Mozilla Thunderbird email clients.

Following successful infiltration, StrelaStealer searches for "logins.json" (account/password) and "key4.db" (password database) within the "%APPDATA%\Thunderbird\Profiles\" directory - by doing so, it can acquire the credentials for Thunderbird.

Alternatively, if Outlook credentials are targeted - StrelaStealer seeks out the Windows Registry from where it can retrieve the program's key and "IMAP User", "IMAP Server", as well as the "IMAP Password" values. Since the latter is kept in an encrypted form, the malicious program employs the Windows CryptUnprotectData feature to decrypt it prior to exfiltration.

SUNBURST

FireEye describes SUNBURST as a trojanized SolarWinds digitally-signed component of the Orion software framework that contains a backdoor that communicates via HTTP to third party servers. After an initial dormant period of up to two weeks, it uses a DGA to generate specific subdomains for a set C&C domain. The backdoor retrieves and executes commands, that include the ability to transfer files, execute files, profile the system, reboot the machine, and disable system services. The C2 traffic to the malicious domains is designed to mimic normal SolarWinds API communications: Orion Improvement Program (OIP) protocol. The backdoor uses multiple obfuscated blocklists to identify forensic and anti-virus tools running as processes, services, and drivers. Multiple trojanzied updates were digitally signed from March - May 2020 and posted to the SolarWinds updates website.

The tag is: *misp-galaxy:malpedia="SUNBURST"*

SUNBURST is also known as:

- Solorigate

SunCrypt

According to PCrisk, Suncrypt ransomware prevents victims from accessing files by encryption. It also renames all encrypted files and creates a ransom message. It renames encrypted files by appending a string of random characters as the new extension.

Supper

Supper is a 64-bit Windows backdoor and tunnelling utility first observed in the wild in July 2024. This malware operates as both a Remote Access Trojan (RAT) and a SOCKS5 proxy, offering threat actors persistent access to infected systems and the ability to route arbitrary traffic through victim environments.

Once executed, it establishes a TCP connection to its primary C2 endpoint, i.e. hardcoded in the file, over port 443. A fallback mechanism allows the malware to retrieve alternate C2 IP addresses from an encoded file, %temp%/s01bafg, ensuring resilience in case the primary server is unavailable. The malware supports up to 16,384 concurrent sessions over a single TCP connection, each uniquely identified via a 16-bit session ID.

Communication begins with an unencrypted 300-byte handshake payload that includes a static bot identifier (0x00691155), system metadata (hostname, domain, OS version, integrity level), and a fixed flag. Following this, all network traffic is wrapped in a 12-byte obfuscated header and an encrypted payload (8 bytes) which consists of two encrypted IP addresses. The header is transformed using two hardcoded XOR keys: 0x4d4d4d4d4d4d4d4d4d and 0x4d4d4d4d. Payload encryption is performed with a non-standard, stateful XOR cipher, where each byte of the message is encrypted based on a calculated offset and a cycling key (xored with 0x4d4d4d4d) derived from the header.

It supports a range of C2 commands, including remote shell execution, session teardown, SOCKS5

proxy operations, self-deletion, and dynamic updating of fallback IPs. When executing commands, Supper spawns a hidden cmd.exe instance and forwards command outputs back to the C2 server after encryption. As a proxy, it accepts operator-specified connection requests, establishes TCP sessions to external targets, and forwards data between the target and the attacker, all managed under the session multiplexing framework.

If instructed or if a C2 session fails, the malware can delete itself using cmd.exe or schtasks.exe, often masquerading the operation under the guise of a scheduled task named "GoogleUpdateTask". The file used to store fallback C2 IPs (%temp%/s01bafg) is updated by the malware using its encryption routine.

Sysraw Stealer

Sysraw stealer got its name because at some point, it was started as "ZSysRaw\sysraw.exe". PDB strings suggest the name "Clipsa" though. First stage connects to /WPCoreLog/, the second one to /WPSecurity/. Its behavior suggest that it is an info stealer. It creates a rather large amount of files in a subdirectory (e.g. data) named "1?[-+].dat" and POSTs them.

Taurus Stealer

According to Zscaler, Taurus is a stealer that surfaced in June 2020. It is being developed by the author(s) that previously created Predator the Thief. The name overlaps partly with the StealerOne / Terra* family (also aliased Taurus Loader) but appears to be a completely disjunct project.

The tag is: *misp-galaxy:malpedia="Taurus Stealer"*

Taurus Stealer is also known as:

tDiscoverer

F-Secure described tDiscoverer (also known as HammerDuke) as interesting because it is written in .NET, and even more so because of its occasional use of Twitter as a C&C communication channel. Some HammerDuke variants only contain a hardcoded C&C server address from which they will retrieve commands, but other HammerDuke variants will first use a custom algorithm to generate a Twitter account name based on the current date. If the account exists, HammerDuke will then search for tweets from that account with links to image files that contain embedded commands for the toolset to execute.

TEARDROP

TEARDROP is a memory only dropper that runs as a service, spawns a thread and reads from the file “gracious_truth.jpg”, which likely has a fake JPG header. Next it checks that HKU\SOFTWARE\Microsoft\CTF exists, decodes an embedded payload using a custom rolling XOR algorithm and manually loads into memory an embedded payload using a custom PE-like file format. TEARDROP does not have code overlap with any previously seen malware. FireEye believe that this was used to execute a customized Cobalt Strike BEACON.

TellYouThePass

According to PCrisk, Tellyouthepass is one of many ransomware-type programs used to block access to files by encryption and keep them in this state unless a ransom is paid.

The program renames all encrypted files by adding the ".locked" extension and creates a ransom message in a text file called "README.html". For example, "1.jpg" is renamed by Tellyouthepass to "1.jpg.locked".

According to cyber criminals, this ransomware encrypts data using RSA-1024 and AES-256 cryptography algorithms.

Terralogger

TerraLogger is a standalone keylogger malware developed by Golden Chickens, a financially motivated threat actor. It uses a common low-level keyboard hook to record keystrokes and writes the logs to local files. The malware is typically delivered as an OCX file and employs initial execution checks before proceeding. Upon execution, it opens a file handle to log keystrokes and implements its keylogger using a SetWindowsHookExA hook. Keystrokes are written to the open log

file, with special characters handled accordingly. Five distinct TerraLogger samples were identified, reflecting minor updates and active development.

TeslaCrypt

According to Kaspersky, detected in February 2015, the new ransomware Trojan gained immediate notoriety as a menace to computer gamers. Amongst other types of target files, it tries to infect typical gaming files: game saves, user profiles, recoded replays etc. That said, TeslaCrypt does not encrypt files that are larger than 268 MB. Recently,
