TFlower is a new ransomware targeting mostly corporate networks discovered in August, 2019. It is reportedly installed on networks by attackers after they gain access via RDP. TFlower displays a console showing activity being performed by the ransomware when it encrypts a machine, further indicating that this ransomware is triggered by the attacker post compromise, similar to Samsam/Samas in terms of TTP. Once encryption is started, the ransomware will conduct a status report to an apparently hard-coded C2. Shadow copies are deleted and the Windows 10 repair environment is disabled by this ransomware. This malware also will terminate any running Outlook.exe process so that the mail files can be encrypted. This ransomware does not add an extention to encrypted files, but prepends the marker "*tflower" and what may be the encrypted encryption key for the file to each affected file. Once encryption is completed, another status report is sent to the C2 server.

TigerLite

TigerLite is a TCP downloader.

It creates mutexes like "qtrgads32" or "Microsoft32".

It uses RC4 with the key "MicrosoftCorporationValidation@#$%^&*()!US" for decryption of its character strings, and a custom algorithm for encryption and decryption of network traffic.

It supports from 5 up to 8 commands with the following identifiers: 1111, 1234, 2099/3333, 4444, 8877, 8888, 9876, 9999. The commands mostly perform various types of execution - either of code received from the server, or native Windows commands, with their output collected and sent back to the server.

TigerLite is an intermediate step of a multi-stage attack, in which Tiger RAT is usually the next step. This malware was observed in attacks against South Korean entities in H1 2021.

The tag is: *misp-galaxy:malpedia="TigerLite"*

Tiger RAT

This is third stage backdoor mentioned in the Kaspersky blog, "Andariel evolves to target South Korea with ransomware". The third stage payload was created via the second stage payload, is interactively executed in the operation and exists in both x64 and x86 versions. Most of them use Internet Explorer or Google Chrome icons and corresponding file names to disguise themselves as legitimate internet browsers. The malware decrypts the embedded payload at runtime. It uses an embedded 16-byte XOR key to decrypt the base64 encoded payload. The decrypted payload is another portable executable file that runs in memory. Before getting decrypted with a hardcoded XOR key, the backdoor also checks for sandbox environment. The backdoor has some code overlap with a know malware family PEBBLEDASH, attributed to Lazarus/LABYRINTH CHOLLIMA.

Tinba

F-Secure notes that TinyBanker or short Tinba is usually distributed through malvertising (advertising content that leads the user to sites hosting malicious threats), exploit kits and spam email campaigns. According to news reports, Tinba has been found targeting bank customers in the United States and Europe.

If Tinba successfully infects a device, it can steal banking and personal information through webinjects. To do this, the malware monitors the user's browser activity and if specific banking portals are visited, Tinba injects code to present the victim with fake web forms designed to mimic the legitimate web site. The malware then tricks them into entering their personal information, log-in credentials, etc in the legitimate-looking page.

Tinba may also display socially-engineered messages to lure or pressure the user into entering their information on the fake page; for example, a message may be shown which attempts to convince the victim that funds were accidentally deposited to his account and must be refunded immediately.

The tag is: *misp-galaxy:malpedia="Tinba"*

Tinba is also known as:

- Illi
- TinyBanker
- Zusy

TinyNuke

TinyNuke (aka Nuclear Bot) is a fully-fledged banking trojan including HiddenDesktop/VNC server and a reverse socks4 server. It was for sale on underground marketplaces for $2500 in 2016. The program's author claimed the malware was written from scratch, but that it functioned similarly to the ZeuS banking trojan in that it could steal passwords and inject arbitrary content when victims visited banking Web sites. However, he then proceeded to destroy his own reputation on hacker forums by promoting his development too aggressively. As a displacement activity, he published his source code on Github. XBot is an off-spring of TinyNuke, but very similar to its ancestor.

The tag is: *misp-galaxy:malpedia="TinyNuke"*

TinyNuke is also known as:

- MicroBankingTrojan
- Nuclear Bot
- NukeBot
- Xbot

TONEDEAF

TONEDEAF is a backdoor that communicates with Command and Control servers using HTTP or DNS. Supported commands include system information collection, file upload, file download, and arbitrary shell command execution. When executed, this variant of TONEDEAF wrote encrypted data to two temporary files – temp.txt and temp2.txt – within the same directory of its execution.

The tag is: *misp-galaxy:malpedia="TONEDEAF"*

TONEDEAF is also known as:

TONERJAM

According to Symantec, Grager was deployed against three organizations in Taiwan, Hong Kong, and Vietnam in April 2024. Analysis of the backdoor revealed that it used the Graph API to communicate with a C&C server hosted on Microsoft OneDrive. Grager was downloaded from a typosquatted URL mimicking the open-source file archiver 7-Zip.

Torisma

Torisma is a complex HTTP(S) downloader, that can serve as an orchestrator handling the execution of additional payloads from the C&C server.

It uses VEST-32 for encryption and decryption of network traffic between the client and the server.

Typically, it uses these parameter names for its HTTP POST requests: ACTION, CODE, CACHE, REQUEST, RES. It sends the victim's MAC address in the initial request.

The response of the server informing the client about a successful authentication is "Your request has been accepted. ClientID: {f9102bc8a7d81ef01ba}". The client then requests additional data from the server, that decrypts to shellcode and its data parameters, and is executed. The client also creates a named pipe, \\.\pipe\fb4d1181bb09b484d058768598b, that allows inter-process communication with the executed shellcode.

Torisma was usually downloaded by NedDnLoader, and deployed in the Operation DreamJob campaigns starting around Q4 2019.

TrickBot

A financial Trojan believed to be a derivative of Dyre: the bot uses very similar code, web injects, and operational tactics. Has multiple modules including VNC and Socks5 Proxy. Uses SSL for C2 communication.

- Q4 2016 - Detected in wild Oct 2016 - 1st Report 2017 - Trickbot primarily uses Necurs as vehicle for installs. Jan 2018 - Use XMRIG (Monero) miner Feb 2018 - Theft Bitcoin Mar 2018 - Unfinished ransomware module Q3/4 2018 - Trickbot starts being spread through Emotet.

Trigona

According to PCrisk, Trigona is ransomware that encrypts files and appends the "._locked" extension to filenames. Also, it drops the "how_to_decrypt.hta" file that opens a ransom note. An example of how Trigona renames files: it renames "1.jpg" to "1.jpg._locked", "2.png" to "2.png._locked", and so forth.

It embeds the encrypted decryption key, the campaign ID, and the victim ID in the encrypted files.

The tag is: *misp-galaxy:malpedia="Trigona"*

Trigona is also known as:

Troldesh

According to Malwarebyte, Ransomware is a type of malware that prevents users from accessing their system or personal files and demands ransom payment in order to regain access. Ransom.Troldesh is spread by malspam, typically in the form of attached .zip files. This ransomware sometimes uses a CMS on a compromised site to host downloads.

The tag is: *misp-galaxy:malpedia="Troldesh"*

Troldesh is also known as:

Tropidoor

Tropidoor is an advanced HTTP/S Remote Access Trojan (RAT) written as a C project, which exhibits significant code overlap with the PostNapTea RAT. In November 2024, it was deployed in campaigns targeting developers via fake recruiters as part of a social engineering campaign distributing trojanized open-source projects on platforms like Bitbucket. It is a final-stage payload in a multi-stage execution chain, which also deployed an obfuscated BeaverTail malware.

The RAT uses RSA and AES for encryption and decryption of network traffic. Communication with the C2 uses specific HTTP POST parameters, including tropi2p, gumi, s_width, and letter, with the first parameter loosely inspiring its code name. It stores its configuration in a binary format and resolves required Windows APIs during runtime via the Fowler–Noll–Vo (FNV) hash function. Many of its characteristic strings are XOR encrypted.

A key technical feature is its custom implementation of various Windows administrative and reconnaissance commands. By implementing this functionality internally, the RAT avoids executing the legitimate Windows binaries, making its command execution activities harder to detect by behavioral monitoring tools. Custom implemented commands include functionality equivalent to standard utilities like:

arp dir ipconfig kill net netsh netstat nslookup ping reg rm sc schtasks systeminfo tracert wmic logicaldisk wmic process

The tag is: *misp-galaxy:malpedia="Tropidoor"*

TsunamiKit

TsunamiKit is a multi-stage malware toolkit written in Python and .NET.

The execution chain consists of several modules—including TsunamiLoader, TsunamiInjector, TsunamiInstaller, TsunamiPayload and the core TsunamiClient. The name is derived from the developer's recurring use of "Tsunami" in its components, e.g. "C# Tsunami Dist Version 3.0.0" or "Tsunami Stable\Tsunami Payload".

The primary purpose of the core module depends on the variant. It either carries out information theft by exfiltrating browser data, or monetize its presence by dropping cryptocurrency miners like XMRig and NBMiner. It also fingerprints the compromised system and uses the Tor network for command-and-control (C&C) communication.

While it was delivered by the InvisibleFerret malware in November 2024, older samples dating back to November 2021 suggest TsunamiKit is a pre-existing dark web project adapted by the APT actors.

Tuoni

According to its Github repo, Tuoni is a sophisticated, cross-platform red teaming framework designed to enhance cybersecurity education and training through large-scale cyber defense exercises. Developed using Java for robustness, Docker for versatility, and featuring an intuitive web browser interface, it supports and streamlines cyber exercises. With its modular, extendable

plugin system, Tuoni offers Red Teamers the flexibility to tailor its capabilities for specific educational and exercise needs. Its user-friendly interface facilitates easy operation and efficient reporting, essential in training environments. Tuoni embodies a commitment to power, adaptability, and collaboration, aimed at empowering Red Teamers with a tool that meets the dynamic demands of modern cyber defense education.

TYPEFRAME

TYPEFRAME is a RAT.

It supports ~25 commands that include operations on the victim's filesystem, manipulation with its configuration, modification of the system's firewall, the download and execution of additional tools from the attacker's C&C and the uninstall via a self-delete batch. The commands are indexed by 16-bit integers, starting with the value 0x8000.

The RAT uses RC4 for decryption of its binary configuration. It has a statically linked OpenSSL 0.9.8k library used for SSL communication.

Unidentified 080

This Trojan is a full-featured RAT capable of executing common tasks such as command execution and downloading/uploading files. This is implemented through a couple dozen C++ classes such as CMFile, CMFile, CMProcess, TFileDownload, TDrive, TProcessInfo, TSock, etc. The first stage custom installer utilizes the same classes. The Trojan uses HTTP Server API to filter HTTPS packets at port 443 and parse commands. It is also used by attackers to gather a target's data, make lateral movements and create SOCKS tunnels to their C2 using the Earthworm tunneler.Given that the Trojan is an HTTPS server itself, the SOCKS tunnel is used for targets without an external IP, so the C2 is able to send commands.

The tag is: *misp-galaxy:malpedia="Unidentified 080"*

Unidentified 121

unidentified_121 acts as a downloader and reflective PE loader, employing a dual-mode execution strategy based on its privilege level. When executed without administrative rights, it uniquely attempts to bypass User Account Control (UAC) by first patching its own Process Environment Block

(PEB) in memory to masquerade as explorer.exe, and then leveraging a specific COM object ({3E5FC7F9-9A51-4367-9063-A120244FBEC7} with the Elevation:Administrator!new: moniker) to relaunch itself with elevated privileges. This initial stage focuses purely on achieving elevation and does not perform C2 communication or direct payload execution itself in the non-elevated state.

Once running with administrative privileges (either initially or after successful elevation), the malware establishes persistence by creating a Scheduled Task named "BlaBlaAgu" using COM, configuring it to run with the highest privileges and repeat every five minutes indefinitely. It actively evades defenses by using PowerShell commands (Add-MpPreference) to add Windows Defender exclusions for its own process and the user's profile directory, reinforcing these exclusions every 60 seconds via a separate thread. Its primary function in this elevated state is to act as a downloader, connecting to its Command and Control (C2) server over TCP port 33334 using a custom protocol encrypted with an RC4-like cipher and the hardcoded key "ALB9SxZBzCqwPFnD"; after a distinct 20-byte client handshake (RC4 Key + integer 444, followed by a 16-byte server response (RC4 Key) for validation), it downloads further encrypted PE payloads and executes them reflectively in its own memory space.

USBCulprit

According to Kaspersky, USBCulprit is a malware that is capable of scanning various paths in victim machines, collecting documents with particular extensions and passing them on to USB drives when they are connected to the system. It can also selectively copy itself to a removable drive in the presence of a particular file, suggesting it can be spread laterally by having designated drives infected and the executable in them opened manually.

vanillarat

Description:

VanillaRat is an advanced remote administration tool coded in C#. VanillaRat uses the Telepathy TCP networking library, dnlib module reading and writing library, and Costura.Fody dll embedding

library. Features:

```
Remote Desktop Viewer (With remote click)
File Browser (Including downloading, drag and drop uploading, and file opening)
Process Manager
Computer Information
Hardware Usage Information (CPU usage, disk usage, available ram)
Message Box Sender
Text To Speech
Screen Locker
Live Keylogger (Also shows current window)
Website Opener
Application Permission Raiser (Normal -> Admin)
Clipboard Text (Copied text)
Chat (Does not allow for client to close form)
Audio Recorder (Microphone)
Process Killer (Task manager, etc.)
Remote Shell
Startup
Security Blacklist (Drag client into list if you don't want connection. Press del. key
on client to remove from list)
```

Varenyky

In May 2019, ESET researchers observed a spike in ESET telemetry data regarding malware targeting France. After further investigations, they identified malware that distributes various types of spam. One of them is leading to a survey that redirects to a dodgy smartphone promotion while the other is a sextortion campaign. The spam targets the users of Orange S.A., a French ISP.

VictoryGate

VictoryGate was the name of a cryptomining botnet, which was disrupted by ESET researchers in April 2020. The used malware itself was also referred to as VictoryGate. It was spotted in May 2019 and targeted mainly Latin American users, specifically, Peru (Criptonizando states 90% of the botnet publication residing there). Both public and private sectors were targeted. This cryptojacking malware was specialized in Monero (XRM) cryptocurrency. VictoryGate shows very strong code overlap with win.orchard.

VIGILANT CLEANER

Wiper malware discovered by Japanese security firm Mitsui Bussan Secure Directions (MBSD), which is assumed to target Japan, the host country of the 2021 Summer Olympics. In addition to targeting common file Office-related files, it specifically targets file types associated with the Japanese word processor Ichitaro.

The tag is: *misp-galaxy:malpedia="VIGILANT CLEANER"*

VIGILANT CLEANER is also known as:

Vjw0rm

VJW0rm (aka Vengeance Justice Worm) is a publicly available, modular JavaScript RAT. Vjw0rm was first released in November 2016 by its primary author, v_B01 (aka Sliemerez), within the prominent DevPoint Arabic-language malware development community. VJW0rm appears to be the JavaScript variant of a series of RATs with identical functionality released by the author throughout late 2016. Other variants include a Visual Basic Script (VBS) based worm titled vw0rm (Vengeance Worm), an AutoHotkey-based tool called vrw0rm (Vengeance Rise Worm), and a PowerShell-based variant called vdw0rm (Vengeance Depth Worm).

Vobfus

Malware of this family searches for computers on a network and creates copies of itself in folders with open access. For the program to be activated, the user must first run it on the computer. The code of this malware is written in the Visual Basic programming language and uses obfuscation, which is a distinguishing feature of this family. Code obfuscation complicates attempts by anti-virus software to analyze suspected malware.

Voldemort

Voldemort is a backdoor discovered by Proofpoint in August 2024. It is being distributed via phishing E-Mails and makes use of creative techniques such as using saved search files during the infection chain for obfuscation and Google Sheets for C2. While its broad targeting looks like it is related to ecrime, Proofpoint notes that the capabilities of the malware point towards espionage/APT activity.

Vyveva RAT

Vyveva is a remote access trojan that uses the Tor library for communication with C&C. Its use of fake TLS for camouflaging the network traffic is one of the typical Lazarus traits.

It uses a simple XOR for encryption of its configuration and network traffic.

It sends detailed information about the victim's environment, like computer name, user name, IP, code page, Windows version, architecture, and time zone.

It supports more than 20 commands that include operations on the victim's filesystem, basic process management, command line execution, file exfiltration, and the download and memory execution of an additional DLL from the C&C (by calling the expected export SamIPromote). As in many RATs from Lazarus arsenal, the commands are indexed by 32-bit integers. The lowest index is 0x3, followed by 0x10, which goes incrementally up to 0x26. Also, it can monitor newly connected drives and the number of logged-on users.

It has MPRD.dll as the internal DLL name, and a single export SamIInitialize.

Vyveva RAT was used in an attack against a freight logistics company in South Africa in June 2020.

wAgentTea

wAgentTea is an HTTP(S) downloader.

It was deployed mostly against South Korean targets like a pharmaceutical company (Q4 2020) or semiconductor industry (Q2 2023). In several cases, the initial access was obtained via exploitation of South Korean software like Initech's INISAFE CrossWeb EX or Dream Security's MagicLine4NX.

It uses AES-128 for encryption and decryption of its network traffic, and for decryption of its binary configuration.

There is a hard-coded list of parameter names used in its HTTP POST request: identy;tname;blogdata;content;thesis;method;bbs;level;maincode;tab;idx;tb;isbn;entry;doc; category;articles;portal

It contains a specific RTTI symbol ".?AVCHttp_socket@@".

WannaCryptor

WannaCry is ransomware that contains a worm component enabled by the EternalBlue exploit. It attempts to use vulnerabilities in the Windows SMBv1 server to remotely compromise systems, encrypt files, and spread to other hosts. Systems that have installed the MS17-010 patch are not vulnerable to the exploits used. The spreading was stopped about 8 hours after initial outbreak due to triggering a kill switch domain.

https://killingthebear.jorgetesta.tech/actors/evil-corp

WastedLocker

WastedLocker is a ransomware detected to be in use since May 2020 by EvilCorp. The ransomware name is derived from the filename that it creates which includes an abbreviation of the victim's name and the string 'wasted'. WastedLocker is protected with a custom crypter, referred to as CryptOne by Fox-IT InTELL. On examination, this crypter turned out to be very basic and was used also by other malware families such as: Netwalker, Gozi ISFB v3, ZLoader and Smokeloader. The crypter mainly contains junk code to increase entropy of the sample and hide the actual code.

The tag is: *misp-galaxy:malpedia="WastedLocker"*

WebbyTea

WebbyTea is an HTTP(S) downloader that uses AES for C&C trafic encryption.

It sends detailed information about the victim's environment, like proxy settings, system instalation date, Windows product name and version, manufacturer, product name, system boot time, time zone, computer name, user name, current time and a list of currently running processes. Data sent to the C&C server consists of the prefix "ci", a 16-characters long hexadecimal string representing the victim ID and an encrypted data about the victim's system. After the payload is acquired from the server and successfully injected in a newly created explorer.exe process, the malware responds back with the same victim ID having the prefix changed to "cs".

The internal DLL name of the native WebbyTea is usually pe64.dll or webT64.dll (from which its name is derived).

The usual payload associated with WebbyTea is SnatchCrypto.

WebMonitor RAT

On its website, Webmonitor RAT is described as 'a very powerful, user-friendly, easy-to-setup and

state-of-the-art monitoring tool. Webmonitor is a fully native RAT, meaning it will run on all Windows versions and languages starting from Windows XP and up, and perfectly compatible with all crypters and protectors.' Unit42 notes in their analysis that it is offered as C2-as-a-service and raises the controversial aspect that the builder allows to create client binaries that will not show any popup or dialogue during installation or while running on a target system.

WhiteBird

According to Dr.Web, WhiteBird is a backdoor written in C++ and designed to operate in both 32-bit and 64-bit Microsoft Windows operating systems. The configuration is encrypted with a single byte XOR key. An interesting feature is that the malware can be restricted to operate only within certain "working_hours" with a granularity of one minute.

The tag is: *misp-galaxy:malpedia="WhiteBird"*

WhiteBird is also known as:

WhiteSnake Stealer

WhiteSnake Stealer, discovered in February 2022, is a sophisticated .NET data-stealing malware that targets browsers, applications, and crypto wallets.

The builder can build payloads in different file formats such as EXE, SCR, COM, CMD, BAT, VBS, PIF, WSF, .hta, MSI, PY, DOC, DOCM, XLS, XLL, XLSM. Some of these (python, bash) allow the malware to run on Linux systems.

The stealer has two execution methods:

- Non-resident - the stealer auto-deletes itself after successful execution
- Resident - the stealer beacons out to the C2 (possibly in the TOR network)

WhiteSnake Stealer can gather system information, execute remote commands, spread through USB drives, and perform tasks like keylogging, file management, and webcam access.

The tag is: *misp-galaxy:malpedia="WhiteSnake Stealer"*

WmRAT

According to Proofpoint, WmRAT is a remote access trojan (RAT) written in C++ that uses sockets for communications and has standard RAT functionality. The RAT can gather basic host information, upload or download files, take screenshots, get geolocation data of the target machine, enumerate directories and files, and run arbitrary commands via cmd or PowerShell. The malware also generates a number of junk threads, potentially to mislead researchers or responders investigating the samples.

XDSpy

According to ESET Research, XDDown is a primary malware component and is strictly a downloader. It persists on the system using the traditional Run key. It downloads additional plugins from the hardcoded C&C server using the HTTP protocol. The HTTP replies contain PE binaries encrypted with a hardcoded two-byte XOR key. Plugins include a module for reconnaissance on the affected system, crawling drives, file exfiltration, SSID gathering, and grabbing saved passwords.

XehookStealer

Xehook is a .NET-based malware targeting Windows systems. It collects data from Chromium and Gecko browsers, supporting over 110 cryptocurrencies and 2FA extensions. CRIL found a potential link between Xehook Stealer, Agniane, and the Cinoshi project, suggesting a progression from a free MaaS model to the development of Xehook Stealer. SmokeLoader binaries were identified as a common vector for distributing Xehook Stealer. Xehook Stealer shares code overlaps with Agniane Stealer, indicating an evolutionary relationship.

XRed

According to eSentire, XRed, also known as Synaptics worm, is a backdoor that has been circulating since at least 2019. This malware was initially spread through drivers bundled with USB-C hub adapters, which served as its primary distribution vector. Once executed, the backdoor self-replicates and to maintain persistence, it creates a Windows Registry Run key. Additionally, it uses a mutex named Synaptics2X to ensure that only one instance of the malware runs at a time. XRed includes several advanced features that enable remote control and data exfiltration. It can download additional payloads from hardcoded URLs embedded within its binary. The malware exfiltrates sensitive system information—such as the MAC address, username, and computer name—which is sent via SMTP to hardcoded email addresses. It also incorporates keylogging functionality through keyboard hooking techniques. Furthermore, XRed supports a variety of remote commands that allow the attacker to gain command prompt access, capture screenshots, list available disks and directories, download files from remote sources, and delete files from the infected system. XRed also exhibits worm-like behavior: It spreads through USB drives by creating an autorun.inf file. Additionally, the malware infects Excel files with macros (.xlsm) by injecting a malicious VBA macro into them. The malware uses a hardcoded dynamic DNS domain (xred.mooo.com) to communicate with its command and control server. This domain serves as an identifying feature of the malware. According to researchers at eSentire, linguistic evidence found in the malware's code suggests that the developer is a native Turkish speaker.

Yanluowang

According to PCrisk, Yanluowang is ransomware that encrypts (and renames) files, ends all running processes, stops services, and creates the "README.txt" file containing a ransom note. It appends the ".yanluowang" extension to filenames. Cybercriminals behind Yanluowang are targeting enterprise entities and organizations in the financial sector.

Files encrypted by Yanluowang can be decrypted with this tool (it is possible to decrypt all files if the original file is larger than 3GB. If the original file is smaller than 3GB, then only smaller files can be decrypted).

The tag is: *misp-galaxy:malpedia="Yanluowang"*

Yanluowang is also known as:

- Dryxiphia

Yunsip

W32/Yunsip!tr.pws is classified as a password stealing trojan. Password Stealing Trojan searches

the infected system for passwords and send them to the hacker.

The tag is: *misp-galaxy:malpedia="Yunsip"*

Yunsip is also known as:

Zacinlo

Bitdefender describes the primary features of the family as follows: Presence of a rootkit driver that protects itself as well as its other components, presence of man-in-the-browser capabilities that intercepts and decrypts SSL communications, and presence of an adware cleanup routine used to remove potential competition in the adware space. It also communicates with its C&C server, sending environment information such as installed AV and other applications. The malware also takes screenshots and does browser redirects, potentially manipulating the DOM tree. It also creates traffic in hidden windows, likely causing adfraud. The malware is generally very configurable and internally makes use of Lua scripts.

The tag is: *misp-galaxy:malpedia="Zacinlo"*

Zacinlo is also known as:

Zebrocy

According to brandefense, Zebrocy is malware that falls into the Trojan category, which the threat actor group APT28/Sofacy has used since 2015. Zebrocy malware consists of 3 main components; Backdoor, Downloader, and Dropper. The Downloader and Dropper take responsibility for discovery processes and downloading the main malware on the systems. At the same time, Backdoor undertakes the duties such as persistence in the system, espionage, and data extraction.

This malware, which is not considered new, has variants in many languages from the past to the present. These include programming languages such as Delphi, C#, Visual C++, VB.net, and Golang. Furthermore, we know advanced threat actors and groups revise their malicious software among their toolkits at certain time intervals using different languages and technologies.

ZeroAccess

ZeroAccess is a modular botnet that was primarily active around 2012. It has been observed selling fake antivirus software to infected users, performing click fraud and deploying bitcoin miners. It

utilizes both peer-to-peer networking and a centralized C&C, spoofing the HTTP Host header with fake DGA-generated domains to confuse researchers. While there is no evidence that the DGA-generated domains were ever intentonally contacted by the malware, faulty middleboxes still caused some requests to be sent to the DGA domains.

The tag is: *misp-galaxy:malpedia="ZeroAccess"*

ZeroAccess is also known as:

ZeroCleare

ZeroCleare is a destructive malware. It has been developed in order to wipe the master boot record section in order to damage a disk's partitioning. Attackers use the EldoS RawDisk driver to perform the malicious action, which is not a signed driver and would therefore not runnable by default. The

attackers managed to install it by using a vulnerable version of VBoxDrv driver, which the DSE accepts and runs. Used to attack middle-east energy and industrial sectors.

ZeroEvil

ZeroEvil is a malware that seems to be distributed by an ARSguarded VBS loader.

It first connects to a gate.php (version=). Upon success, an embedded VBS gets started connecting to logs_gate.php (plugin=, report=). So far, only one embedded VBS was observed: it creates and starts a PowerShell script to retrieve all password from the Windows.Security.Credentials.PasswordVault. Apart from that, a screenshot is taken and a list of running processes generated.

The ZeroEvil executable contains multiple DLLs, sqlite3.dll, ze_core.DLL (Mutex) and ze_autorun.DLL (Run-Key).

Zeus OpenSSL

This family describes the Zeus-variant that includes a version of OpenSSL and usually is downloaded by Zloader.

In June 2016, the version 1.5.4.0 (PE timestamp: 2016.05.11) appeared, downloaded by Zloader (known as DEloader at that time). OpenSSL 1.0.1p is statically linked to it, thus its size is roughly 1.2 MB. In subsequent months, that size increased up to 1.6 MB. In January 2017, with version 1.14.8.0, OpenSSL 1.0.2j was linked to it, increasing the size to 1.8 MB. Soon after also in January 2017, with version v1.15.0.0 the code was obfuscated, blowing up the size of the binary to 2.2 MB.

Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

The tag is: *misp-galaxy:malpedia="Zeus OpenSSL"*

Zeus OpenSSL is also known as:

- XSphinx

Zeus Sphinx

This family describes the vanilla Zeus-variant that includes TOR (and Polipo proxy). It has an almost

90% overlap with Zeus v2.0.8.9. Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

Zloader

This family describes the (initially small) loader, which downloads Zeus OpenSSL.

In June 2016, a new loader was dubbed DEloader by Fortinet. It has some functions borrowed from Zeus 2.0.8.9 (e.g. the versioning, nrv2b, binstorage-labels), but more importantly, it downloaded a Zeus-like banking trojan (→ Zeus OpenSSL). Furthermore, the loader shared its versioning with the Zeus OpenSSL it downloaded. The initial samples from May 2016 were small (17920 bytes). At some point, visualEncrypt/Decrypt was added, e.g. in v1.11.0.0 (September 2016) with size 27648 bytes. In

January 2017 with v1.15.0.0, obfuscation was added, which blew the size up to roughly 80k, and the loader became known as Zloader aka Terdot. These changes may be related to the Moskalvzapoe Distribution Network, which started the distribution of it at the same time.

Please note that IBM X-Force decided to call win.zloader/win.zeus_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus_openssl - the X to refer to IBM X-Force.

The tag is: *misp-galaxy:malpedia="Zloader"*

Zloader is also known as:

- DELoader
- SILENTNIGHT
- Terdot

ZXShell

According to FireEye, ZXSHELL is a backdoor that can be downloaded from the internet, particularly Chinese hacker websites. The backdoor can launch port scans, run a keylogger, capture screenshots, set up an HTTP or SOCKS proxy, launch a reverse command shell, cause SYN floods, and transfer/delete/run files. The publicly available version of the tool provides a graphical user interface that malicious actors can use to interact with victim backdoors. Simplified Chinese is the language used for the bundled ZXSHELL documentation.

The tag is: *misp-galaxy:malpedia="ZXShell"*

ZXShell is also known as:

- Sensocode

Zyklon

According to FireEye, Zyklon or Zyklon HTTP is a publicly available, full-featured backdoor capable of keylogging, password harvesting, downloading and executing additional plugins, conducting distributed denial-of-service (DDoS) attacks, and self-updating and self-removal. The malware may communicate with its command and control (C2) server over The Onion Router (Tor) network if configured to do so. The malware can download several plugins, some of which include features such as cryptocurrency mining and password recovery, from browsers and email software. Zyklon also provides a very efficient mechanism to monitor the spread and impact.

Microsoft Activity Group actor

Activity groups as described by Microsoft.

Microsoft Activity Group actor is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

Various

PROMETHIUM

PROMETHIUM is an activity group that has been active as early as 2012. The group primarily uses Truvasys, a first-stage malware that has been in circulation for several years. Truvasys has been involved in several attack campaigns, where it has masqueraded as one of server common computer utilities, including WinUtils, TrueCrypt, WinRAR, or SanDisk. In each of the campaigns, Truvasys malware evolved with additional features—this shows a close relationship between the activity groups behind the campaigns and the developers of the malware.

NEODYMIUM

NEODYMIUM is an activity group that is known to use a backdoor malware detected by Microsoft as Wingbird. This backdoor's characteristics closely match FinFisher, a government-grade commercial surveillance package. Data about Wingbird activity indicate that it is typically used to attack individual computers instead of networks.

TERBIUM

Microsoft Threat Intelligence identified similarities between this recent attack and previous 2012 attacks against tens of thousands of computers belonging to organizations in the energy sector. Microsoft Threat Intelligence refers to the activity group behind these attacks as TERBIUM, following our internal practice of assigning rogue actors chemical element names.

STRONTIUM

STRONTIUM has been active since at least 2007. Whereas most modern untargeted malware is ultimately profit-oriented, STRONTIUM mainly seeks sensitive information. Its primary institutional targets have included government bodies, diplomatic institutions, and military forces and installations in NATO member states and certain Eastern European countries. Additional targets have included journalists, political advisors, and organizations associated with political activism in central Asia. STRONTIUM is an activity group that usually targets government agencies, diplomatic institutions, and military organizations, as well as affiliated private sector organizations such as defense contractors and public policy research institutes. Microsoft has attributed more 0-day exploits to STRONTIUM than any other tracked group in 2016. STRONTIUM frequently uses compromised e-mail accounts from one victim to send malicious e-mails to a second victim and will persistently pursue specific targets for months until they are successful in compromising the victims' computer.

The tag is: *misp-galaxy:microsoft-activity-group="STRONTIUM"*

STRONTIUM is also known as:

- APT 28
- APT28
- Pawn Storm
- Fancy Bear
- Sednit
- TsarTeam
- TG-4127
- Group-4127
- Sofacy
- Grey-Cloud

PLATINUM

PLATINUM has been targeting its victims since at least as early as 2009, and may have been active for several years prior. Its activities are distinctly different not only from those typically seen in untargeted attacks, but from many targeted attacks as well. A large share of targeted attacks can be characterized as opportunistic: the activity group changes its target profiles and attack geographies based on geopolitical seasons, and may attack institutions all over the world. Like many such groups, PLATINUM seeks to steal sensitive intellectual property related to government interests, but its range of preferred targets is consistently limited to specific governmental organizations, defense institutes, intelligence agencies, diplomatic institutions, and telecommunication providers in South and Southeast Asia. The group's persistent use of spear phishing tactics (phishing attempts aimed at specific individuals) and access to previously undiscovered zero-day exploits have made it a highly resilient threat.

BARIUM

Microsoft Threat Intelligence associates Winnti with multiple activity groups—collections of malware, supporting infrastructure, online personas, victimology, and other attack artifacts that the Microsoft intelligent security graph uses to categorize and attribute threat activity. Microsoft labels activity groups using code names derived from elements in the periodic table. In the case of this malware, the activity groups strongly associated with Winnti are BARIUM and LEAD. But even though they share the use of Winnti, the BARIUM and LEAD activity groups are involved in very different intrusion scenarios. BARIUM begins its attacks by cultivating relationships with potential

victims—particularly those working in Business Development or Human Resources—on various social media platforms. Once BARIUM has established rapport, they spear-phish the victim using a variety of unsophisticated malware installation vectors, including malicious shortcut (.lnk) files with hidden payloads, compiled HTML help (.chm) files, or Microsoft Office documents containing macros or exploits. Initial intrusion stages feature the Win32/Barlaiy implant—notable for its use of social network profiles, collaborative document editing sites, and blogs for C&C. Later stages of the intrusions rely upon Winnti for persistent access. The majority of victims recorded to date have been in electronic gaming, multimedia, and Internet content industries, although occasional intrusions against technology companies have occurred.

Links
https://blogs.technet.microsoft.com/mmpc/2017/01/25/detecting-threat-actors-in-recent-german-industrial-attacks-with-windows-defender-atp/

LEAD

In contrast, LEAD has established a far greater reputation for industrial espionage. In the past few years, LEAD's victims have included: Multinational, multi-industry companies involved in the manufacture of textiles, chemicals, and electronics Pharmaceutical companies A company in the chemical industry University faculty specializing in aeronautical engineering and research A company involved in the design and manufacture of motor vehicles A cybersecurity company focusing on protecting industrial control systems During these intrusions, LEAD's objective was to steal sensitive data, including research materials, process documents, and project plans. LEAD also steals code-signing certificates to sign its malware in subsequent attacks. In most cases, LEAD's attacks do not feature any advanced exploit techniques. The group also does not make special effort to cultivate victims prior to an attack. Instead, the group often simply emails a Winnti installer to potential victims, relying on basic social engineering tactics to convince recipients to run the attached malware. In some other cases, LEAD gains access to a target by brute-forcing remote access login credentials, performing SQL injection, or exploiting unpatched web servers, and then they copy the Winnti installer directly to compromised machines.

The tag is: *misp-galaxy:microsoft-activity-group="LEAD"*

GALLIUM

Microsoft Threat Intelligence Center (MSTIC) is raising awareness of the ongoing activity by a group we call GALLIUM, targeting telecommunication providers. When Microsoft customers have been targeted by this activity, we notified them directly with the relevant information they need to protect themselves. By sharing the detailed methodology and indicators related to GALLIUM activity, we're encouraging the security community to implement active defenses to secure the broader ecosystem from these attacks. To compromise targeted networks, GALLIUM target unpatched internet-facing services using publicly available exploits and have been known to target vulnerabilities in WildFly/JBoss. Once persistence is established in a network, GALLIUM uses common techniques and tools like Mimikatz to obtain credentials that allows for lateral movement across the target network. Within compromised networks, GALLIUM makes no attempt to obfuscate their intent and are known to use common versions of malware and publicly available toolkits with small modifications. The operators rely on low cost and easy to replace infrastructure that consists of dynamic-DNS domains and regularly reused hop points. This activity from GALLIUM has been identified predominantly through 2018 to mid-2019. GALLIUM is still active; however, activity levels have dropped when compared to what was previously observed.

The tag is: *misp-galaxy:microsoft-activity-group="GALLIUM"*

GALLIUM is also known as:

- Operation Soft Cell

View relationships graph

GALLIUM has relationships with:

- similar: misp-galaxy:threat-actor="Operation Soft Cell" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:threat-actor="GALLIUM" with estimative-language:likelihood-probability="almost-certain"

PARINACOTA

One actor that has emerged in this trend of human-operated attacks is an active, highly adaptive group that frequently drops Wadhrama as payload. PARINACOTA impacts three to four organizations every week and appears quite resourceful: during the 18 months that we have been monitoring it, we have observed the group change tactics to match its needs and use compromised machines for various purposes, including cryptocurrency mining, sending spam emails, or proxying for other attacks. The group's goals and payloads have shifted over time, influenced by the type of compromised infrastructure, but in recent months, they have mostly deployed the Wadhrama ransomware. The group most often employs a smash-and-grab method, whereby they attempt to infiltrate a machine in a network and proceed with subsequent ransom in less than an hour. There are outlier campaigns in which they attempt reconnaissance and lateral movement, typically when they land on a machine and network that allows them to quickly and easily move throughout the environment. PARINACOTA's attacks typically brute forces their way into servers that have Remote Desktop Protocol (RDP) exposed to the internet, with the goal of moving laterally inside a network or performing further brute-force activities against targets outside the network. This allows the group to expand compromised infrastructure under their control. Frequently, the group targets built-in local administrator accounts or a list of common account names. In other instances, the group targets Active Directory (AD) accounts that they compromised or have prior knowledge of, such as service accounts of known vendors. The group adopted the RDP brute force technique that the older ransomware called Samas (also known as SamSam) infamously used. Other malware families like GandCrab, MegaCortext, LockerGoga, Hermes, and RobbinHood have also used this method in targeted ransomware attacks. PARINACOTA, however, has also been observed to adapt to any path of least resistance they can utilize. For instance, they sometimes discover unpatched systems and use disclosed vulnerabilities to gain initial access or elevate privileges.

The tag is: *misp-galaxy:microsoft-activity-group="PARINACOTA"*

View relationships graph

PARINACOTA has relationships with:

- uses: misp-galaxy:ransomware="Wadhrama" with estimative-language:likelihood-probability="likely"
- similar: misp-galaxy:threat-actor="PARINACOTA" with estimative-language:likelihood-probability="almost-certain"

GADOLINIUM

GADOLINIUM is a nation-state activity group that has been compromising targets for nearly a decade with a worldwide focus on the maritime and health industries. As with most threat groups, GADOLINIUM tracks the tools and techniques of security practitioners looking for new techniques they can use or modify to create new exploit methods. Historically, GADOLINIUM used custom-crafted malware families that analysts can identify and defend against. In response, over the last year GADOLINIUM has begun to modify portions of its toolchain to use open-source toolkits to obfuscate their activity and make it more difficult for analysts to track. Because cloud services frequently offer a free trial or one-time payment (PayGo) account offerings, malicious actors have found ways to take advantage of these legitimate business offerings. By establishing free or PayGo accounts, they can use cloud-based technology to create a malicious infrastructure that can be established quickly then taken down before detection or given up at little cost.

The tag is: *misp-galaxy:microsoft-activity-group="GADOLINIUM"*

HAFNIUM

HAFNIUM primarily targets entities in the United States across a number of industry sectors, including infectious disease researchers, law firms, higher education institutions, defense contractors, policy think tanks, and NGOs. HAFNIUM has previously compromised victims by exploiting vulnerabilities in internet-facing servers, and has used legitimate open-source frameworks, like Covenant, for command and control. Once they’ve gained access to a victim

network, HAFNIUM typically exfiltrates data to file sharing sites like MEGA. In campaigns unrelated to these vulnerabilities, Microsoft has observed HAFNIUM interacting with victim Office 365 tenants. While they are often unsuccessful in compromising customer accounts, this reconnaissance activity helps the adversary identify more details about their targets' environments. HAFNIUM operates primarily from leased virtual private servers (VPS) in the United States.

Misinformation Pattern

AM!TT Technique.

Misinformation Pattern is a cluster galaxy available in JSON format at **this location** The JSON format can be freely reused in your application or automatically enabled in MISP.

authors

misinfosecproject

5Ds (dismiss, distort, distract, dismay, divide)

Nimmo's "4Ds of propaganda": dismiss, distort, distract, dismay (MisinfosecWG added divide in 2019). Misinformation promotes an agenda by advancing narratives supportive of that agenda. This is most effective when the advanced narrative pre-dates the revelation of the specific misinformation content. But this is often not possible.

The tag is: *misp-galaxy:amitt-misinformation-pattern="5Ds (dismiss, distort, distract, dismay, divide)"*

Table 5791. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0001.md

Facilitate State Propaganda

Organize citizens around pro-state messaging. Paid or volunteer groups coordinated to push state propaganda (examples include 2016 Diba Facebook Expedition, coordinated to overcome China's Great Firewall to flood the Facebook pages of Taiwanese politicians and news agencies with a pro-PRC message).

The tag is: *misp-galaxy:amitt-misinformation-pattern="Facilitate State Propaganda"*

Table 5792. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0002.md

Leverage Existing Narratives

Use or adapt existing narrative themes, where narratives are the baseline stories of a target audience. Narratives form the bedrock of our worldviews. New information is understood through a process firmly grounded in this bedrock. If new information is not consitent with the prevailing narratives of an audience, it will be ignored. Effective campaigns will frame their misinformation in the context of these narratives. Highly effective campaigns will make extensive use of audience-appropriate archetypes and meta-narratives throughout their content creation and amplifiction practices. Examples include midwesterners are generous, Russia is under attack from outside.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Leverage Existing Narratives"*

Table 5793. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0003.md

Competing Narratives

Advance competing narratives connected to same issue ie: on one hand deny incident while at same time expresses dismiss. MH17 (example) "Russian Foreign Ministry again claimed that "absolutely groundless accusations are put forward against the Russian side, which are aimed at discrediting Russia in the eyes of the international community" (deny); "The Dutch MH17 investigation is biased, anti-Russian and factually inaccurate" (dismiss).

Suppressing or discouraging narratives already spreading requires an alternative. The most simple set of narrative techniques in response would be the construction and promotion of contradictory alternatives centered on denial, deflection, dismissal, counter-charges, excessive standards of proof, bias in prohibition or enforcement, and so on.

These competing narratives allow loyalists cover, but are less compelling to opponents and fence-sitters than campaigns built around existing narratives or highly explanatory master narratives. Competing narratives, as such, are especially useful in the "firehose of misinformation" approach.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Competing Narratives"*

Table 5794. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0004.md

Center of Gravity Analysis

Recon/research to identify "the source of power that provides moral or physical strength, freedom of action, or will to act." Thus, the center of gravity is usually seen as the "source of strength". Includes demographic and network analysis of communities

The tag is: *misp-galaxy:amitt-misinformation-pattern="Center of Gravity Analysis"*

Table 5795. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0005.md

Create Master Narratives

The promotion of beneficial master narratives is perhaps the most effective method for achieving long-term strategic narrative dominance. From a "whole of society" perpective the promotion of the society's core master narratives should occupy a central strategic role. From a misinformation campaign / cognitive security perpectve the tactics around master narratives center more precisely on the day-to-day promotion and reinforcement of this messaging. In other words, beneficial, high-coverage master narratives are a central strategic goal and their promotion consitutes an ongoing tactical struggle carried out at a whole-of-society level.

By way of example, major powers are promoting master narratives such as: * "Huawei is detetmined to build trustworthy networks" * "Russia is the victim of bullying by NATO powers" * "USA is guided by its founding principles of liberty and egalitarianism"

Tactically, their promotion covers a broad spectrum of activities both on- and offline.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create Master Narratives"*

Table 5796. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0006.md

Create fake Social Media Profiles / Pages / Groups

Create key social engineering assets needed to amplify content, manipulate algorithms, fool public and/or specific incident/campaign targets.

Computational propaganda depends substantially on false perceptions of credibility and

acceptance. By creating fake users and groups with a variety of interests and commitments, attackers can ensure that their messages both come from trusted sources and appear more widely adopted than they actually are.

Examples: Ukraine elections (2019) circumvent Facebook's new safeguards by paying Ukrainian citizens to give a Russian agent access to their personal pages. EU Elections (2019) Avaaz reported more than 500 suspicious pages and groups to Facebook related to the three-month investigation of Facebook disinformation networks in Europe. Mueller report (2016) The IRA was able to reach up to 126 million Americans on Facebook via a mixture of fraudulent accounts, groups, and advertisements, the report says. Twitter accounts it created were portrayed as real American voices by major news outlets. It was even able to hold real-life rallies, mobilizing hundreds of people at a time in major cities like Philadelphia and Miami.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake Social Media Profiles / Pages / Groups"*

Table 5797. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0007.md

Create fake or imposter news sites

Modern computational propaganda makes use of a cadre of imposter news sites spreading globally. These sites, sometimes motivated by concerns other than propaganda—for instance, click-based revenue—often have some superficial markers of authenticity, such as naming and site-design. But many can be quickly exposed with reference to their owenership, reporting history and adverstising details. A prominent case from the 2016 era was the *Denver Guardian*, which purported to be a local newspaper in Colorado and specialized in negative stories about Hillary Clinton.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake or imposter news sites"*

Table 5798. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0008.md

Create fake experts

Stories planted or promoted in computational propaganda operations often make use of experts fabricated from whole cloth, sometimes specifically for the story itself. For example, in the Jade Helm conspiracy theory promoted by SVR in 2015, a pair of experts—one of them naming himself a "Military Intelligence Analyst / Russian Regional CME" and the other a "Geopolitical Strategist, Journalist & Author"--pushed the story heavily on LinkedIn.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake experts"*

Table 5799. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0009.md

Cultivate useful idiots

Cultivate propagandists for a cause, the goals of which are not fully comprehended, and who are used cynically by the leaders of the cause. Independent actors use social media and specialised web sites to strategically reinforce and spread messages compatible with their own. Their networks are infiltrated and used by state media disinformation organisations to amplify the state's own disinformation strategies against target populations. Many are traffickers in conspiracy theories or hoaxes, unified by a suspicion of Western governments and mainstream media. Their narratives, which appeal to leftists hostile to globalism and military intervention and nationalists against immigration, are frequently infiltrated and shaped by state-controlled trolls and altered news items from agencies such as RT and Sputnik. Also know as "useful idiots" or "unwitting agents".

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cultivate useful idiots"*

Table 5800. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0010.md

Hijack legitimate account

Hack or take over legimate accounts to distribute misinformation or damaging content. Examples include Syrian Electronic Army (2013) series of false tweets from a hijacked Associated Press Twitter account claiming that President Barack Obama had been injured in a series of explosions near the White House. The false report caused a temporary plunge of 143 points on the Dow Jones Industrial Average.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Hijack legitimate account"*

Table 5801. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0011.md

Use concealment

Use anonymous social media profiles. Examples include page or group administrators, masked "whois" website directory data, no bylines connected to news article, no masthead connect to news websites.

Example is 2016 @TEN_GOP profile where the actual Tennessee Republican Party tried unsuccessfully for months to get Twitter to shut it down, and 2019 Endless Mayfly is an Iran-aligned network of inauthentic personas and social media accounts that spreads falsehoods and amplifies narratives critical of Saudi Arabia, the United States, and Israel.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Use concealment"*

Table 5802. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0012.md

Create fake websites

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake websites"*

Table 5803. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0013.md

Create funding campaigns

Generate revenue through online funding campaigns. e.g. Gather data, advance credible persona via Gofundme; Patreon; or via fake website connecting via PayPal or Stripe. (Example 2016) #VaccinateUS Gofundme campaigns to pay for Targetted facebook ads (Larry Cook, targetting Washington State mothers, $1,776 to boost posts over 9 months).

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create funding campaigns"*

Table 5804. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0014.md

Create hashtag

Many incident-based campaigns will create a hashtag to promote their fabricated event (e.g. #ColumbianChemicals to promote a fake story about a chemical spill in Louisiana).

Creating a hashtag for an incident can have two important effects: 1. Create a perception of reality around an event. Certainly only "real" events would be discussed in a hashtag. After all, the event has a name! 2. Publicize the story more widely through trending lists and search behavior

Asset needed to direct/control/manage "conversation" connected to launching new incident/campaign with new hashtag for applicable social media sites ie: Twitter, LinkedIn)

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create hashtag"*

Table 5805. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0015.md

Clickbait

Create attention grabbing headlines (outrage, doubt, humor) required to drive traffic & engagement. (example 2016) “Pope Francis shocks world, endorses Donald Trump for president.” (example 2016) "FBI director received millions from Clinton Foundation, his brother’s law firm does Clinton’s taxes”. This is a key asset

The tag is: *misp-galaxy:amitt-misinformation-pattern="Clickbait"*

Table 5806. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0016.md

Promote online funding

Drive traffic/engagement to funding campaign sites; helps provide measurable metrics to assess conversion rates

The tag is: *misp-galaxy:amitt-misinformation-pattern="Promote online funding"*

Table 5807. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0017.md

Paid targeted ads

Create or fund advertisements targeted at specific populations

The tag is: *misp-galaxy:amitt-misinformation-pattern="Paid targeted ads"*

Table 5808. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0018.md

Generate information pollution

Flood social channels; drive traffic/engagement to all assets; create aura/sense/perception of pervasiveness/consensus (for or against or both simultaneously) of an issue or topic. "Nothing is true, but everything is possible." Akin to astroturfing campaign.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Generate information pollution"*

Table 5809. Table References

Links

https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0019.md

Trial content

Iteratively test incident performance (messages, content etc), e.g. A/B test headline/content enagagement metrics; website and/or funding campaign conversion rates

The tag is: *misp-galaxy:amitt-misinformation-pattern="Trial content"*

Table 5810. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0020.md

Memes

Memes are one of the most important single artefact types in all of computational propaganda. Memes in this framework denotes the narrow image-based definition. But that naming is no accident, as these items have most of the important properties of Dawkins' original conception as a self-replicating unit of culture. Memes pull together reference and commentary; image and narrative; emotion and message. Memes are a powerful tool and the heart of modern influence campaigns.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Memes"*

Table 5811. Table References

Conspiracy narratives

"Conspiracy narratives appeal to the human desire for explanatory order, by invoking the participation of poweful (often sinister) actors in pursuit of their own political goals. These narratives are especially appealing when an audience is low-information, marginalized or otherwise inclined to reject the prevailing explanation. Conspiracy narratives are an important component of the ""firehose of falsehoods"" model.

Example: QAnon: conspiracy theory is an explanation of an event or situation that invokes a conspiracy by sinister and powerful actors, often political in motivation, when other explanations are more probable "

The tag is: *misp-galaxy:amitt-misinformation-pattern="Conspiracy narratives"*

Table 5812. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0022.md

Distort facts

Change, twist, or exaggerate existing facts to construct a narrative that differs from reality. Examples: images and ideas can be distorted by being placed in an improper content

The tag is: *misp-galaxy:amitt-misinformation-pattern="Distort facts"*

Table 5813. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0023.md

Create fake videos and images

Create fake videos and/or images by manipulating existing content or generating new content (e.g. deepfakes). Examples include Pelosi video (making her appear drunk) and photoshoped shark on flooded streets of Houston TX.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake videos and images"*

Table 5814. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0024.md

Leak altered documents

Obtain documents (eg by theft or leak), then alter and release, possibly among factual documents/sources.

Example (2019) DFRLab report "Secondary Infektion" highlights incident with key asset being a forged "letter" created by the operation to provide ammunition for far-right forces in Europe ahead of the election.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Leak altered documents"*

Table 5815. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0025.md

Create fake research

Create fake academic research. Example: fake social science research is often aimed at hot-button social issues such as gender, race and sexuality. Fake science research can target Climate Science debate or pseudoscience like anti-vaxx

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake research"*

Table 5816. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0026.md

Adapt existing narratives

Adapting existing narratives to current operational goals is the tactical sweet-spot for an effective misinformation campaign. Leveraging existing narratives is not only more effective, it requires substantially less resourcing, as the promotion of new master narratives operates on a much larger scale, both time and scope. Fluid, dynamic & often interchangable key master narratives can be ("The morally corrupt West") adapted to divisive (LGBT proganda) or to distort (individuals working as CIA operatives). For Western audiences, different but equally powerful framings are available, such as "USA has a fraught history in race relations, espically in crimincal justice areas."

The tag is: *misp-galaxy:amitt-misinformation-pattern="Adapt existing narratives"*

Table 5817. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0027.md

Create competing narratives

"Misinformation promotes an agenda by advancing narratives supportive of that agenda. This is most effective when the advanced narrative pre-dates the revelation of the specific misinformation content. But this is often not possible.

Suppressing or discouraging narratives already spreading requires an alternative. The most simple set of narrative techniques in response would be the construction and promotion of contradictory alternatives centered on denial, deflection, dismissal, counter-charges, excessive standards of proof, bias in prohibition or enforcement, and so on.

These competing narratives allow loyalists cover, but are less compelling to opponents and fence-sitters than campaigns built around existing narratives or highly explanatory master narratives. Competing narratives, as such, are especially useful in the ""firehose of misinformation"" approach."

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create competing narratives"*

Table 5818. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0028.md

Manipulate online polls

Create fake online polls, or manipulate existing online polls. Examples: flooding FCC with

comments; creating fake engagement metrics of Twitter/Facebook polls to manipulate perception of given issue. Data gathering tactic to target those who engage, and potentially their networks of friends/followers as well

The tag is: *misp-galaxy:amitt-misinformation-pattern="Manipulate online polls"*

Table 5819. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0029.md

Backstop personas

Create other assets/dossier/cover/fake relationships and/or connections or documents, sites, bylines, attributions, to establish/augment/inflate crediblity/believability

The tag is: *misp-galaxy:amitt-misinformation-pattern="Backstop personas"*

https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0045.md

Search Engine Optimization

Manipulate content engagement metrics (ie: Reddit & Twitter) to influence/impact news search results (e.g. Google), also elevates RT & Sputnik headline into Google news alert emails. aka "Black-hat SEO"

The tag is: *misp-galaxy:amitt-misinformation-pattern="Search Engine Optimization"*

Table 5836. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0046.md

Muzzle social media as a political force

Use political influence or the power of state to stop critical social media comments. Government requested/driven content take downs (see Google Transperancy reports. (Example 20190 Singapore Protection from Online Falsehoods and Manipulation Bill would make it illegal to spread "false statements of fact" in Singapore, where that information is "prejudicial" to Singapore's security or "public tranquility." Or India/New Delhi has cut off services to Facebook and Twitter in Kashmir 28 times in the past five years, and in 2016, access was blocked for five months — on the grounds that these platforms were being used for anti-social and "anti-national" purposes.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Muzzle social media as a political force"*

Table 5837. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0047.md

Cow online opinion leaders

Intimidate, coerce, threaten critics/dissidents/journalists via trolling, doxing. Phillipines (example) Maria Ressa and Rappler journalists targeted Duterte regime, lawsuits, trollings, banned from the presidential palace where press briefings take place. 2017 Bot attack on five ProPublica Journalists.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cow online opinion leaders"*

Table 5838. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0048.md

Flooding

Flooding and/or mobbing social media channels feeds and/or hashtag with excessive volume of content to control/shape online conversations and/or drown out opposing points of view. Bots and/or patriotic trolls are effective tools to acheive this effect.

Example (2018): bots flood social media promoting messages which support Saudi Arabia with intent to cast doubt on allegations that the kingdom was involved in Khashoggi's death.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Flooding"*

Table 5839. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0049.md

Cheerleading domestic social media ops

Deploy state-coordinated social media commenters and astroturfers. Both internal/domestic and external social media influence operations, popularized by China (50cent Army manage message inside the "Great Firewall") but also technique used by Chinese English-language social media influence operations are seeded by state-run media, which overwhelmingly present a positive, benign, and cooperative image of China.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cheerleading domestic social media ops"*

Table 5840. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0050.md

Fabricate social media comment

Use government-paid social media commenters, astroturfers, chat bots (programmed to reply to specific key words/hashtags) influence online conversations, product reviews, web-site comment forums. (2017 example) the FCC was inundated with nearly 22 million public comments on net neutrality (many from fake accounts)

The tag is: *misp-galaxy:amitt-misinformation-pattern="Fabricate social media comment"*

Table 5841. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0051.md

Tertiary sites amplify news

Create content/news/opinion web-sites to cross-post stories. Tertiary sites circulate and amplify narratives. Often these sites have no masthead, bylines or attribution.

Examples of tertiary sites inculde Russia Insider, The Duran, geopolitica.ru, Mint Press News, Oriental Review, globalresearch.ca.

Example (2019, Domestic news): Snopes reveals Star News Digital Media, Inc. may look like a media company that produces local news, but operates via undisclosed connections to political activism.

Example (2018) FireEye reports on Iranian campaign that created between April 2018 and March 2019 sites used to spread inauthentic content from websites such as Liberty Front Press (LFP), US Journal, and Real Progressive Front during the US mid-terms.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Tertiary sites amplify news"*

Table 5842. Table References

Links

https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0052.md

Twitter trolls amplify and manipulate

Use trolls to amplify narratives and/or manipulate narratives. Fake profiles/sockpuppets operating to support individuals/narratives from the entire political spectrum (left/right binary). Operating with increased emphasis on promoting local content and promoting real Twitter users generating their own, often divisive political content, as it's easier to amplify existing content than create new/original content. Trolls operate where ever there's a socially divisive issue (issues that can/are be politicized) e.g. BlackLivesMatter or MeToo

The tag is: *misp-galaxy:amitt-misinformation-pattern="Twitter trolls amplify and manipulate"*

Table 5843. Table References

Links
https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0053.md

Twitter bots amplify

Use bots to amplify narratives above algorithm thresholds. Bots are automated/programmed profiles designed to amplify content (ie: automatically retweet or like) and give appearance it's more "popular" than it is. They can operate as a network, to function in a coordinated/orchestrated manner. In some cases (more so now) they are an inexpensive/disposable assets used for minimal deployment as bot detection tools improve and platforms are more responsive.(example 2019) #TrudeauMustGo

The tag is: *misp-galaxy:amitt-misinformation-pattern="Twitter bots amplify"*

Table 5844. Table References

https://attack.mitre.org/detectionstrategies/DET0003#AN0007

Analytic 0008 - AN0008

macOS clients joined to AD via LDAP may script account provisioning via `dsconfigad`, `dscl`, or LDAP scripts. Detection occurs when such tools run on a domain-joined system, followed by authentication attempts by a previously unseen account.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0008 - AN0008"*

Table 5875. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0003#AN0008

Analytic 0800 - AN0800

Correlates suspicious removal or modification of the com.apple.quarantine extended attribute, manipulation of LSFileQuarantineEnabled values in Info.plist, and unexpected process execution of unsigned or non-notarized binaries. Also monitors abnormal trust validation failures in unified logs and unusual activity in QuarantineEvents database entries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0800 - AN0800"*

Table 5876. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0288#AN0800

Analytic 0080 - AN0080

Processes invoking network-intensive child processes or uploading large data volumes, often from non-standard user or system contexts, with evidence of long-duration TCP/UDP sessions to unusual destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0080 - AN0080"*

Table 5877. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0028#AN0080

Analytic 0090 - AN0090

Binaries or applications executed with tampered or unverifiable code signatures. Often tied to Gatekeeper bypasses, App Translocation, or use of unsigned launch daemons by untrusted users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0090 - AN0090"*

Table 5878. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0031#AN0090

Analytic 0900 - AN0900

Adversaries use cloud API, CLI, or console to create IAM users or roles. Initial CreateUser is followed by policy/role attachment. Detection monitors temporal chains involving IAM:CreateUser, AttachUserPolicy, and credential generation, especially from automation or foreign IP ranges.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0900 - AN0900"*

Table 5879. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0319#AN0900

Analytic 0009 - AN0009

Abnormal modification of the PATH environment variable or registry keys controlling system paths, combined with execution of binaries named after legitimate system tools from user-writable directories. Defender correlates registry modifications, file creation of suspicious binaries, and process execution paths inconsistent with baseline system directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0009 - AN0009"*

Table 5880. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0004#AN0009

Analytic 0110 - AN0110

Monitor /var/log/audit/audit.log and DNS resolver logs for repeated failed lookups or connections to high-entropy domain names. Correlate suspicious DNS queries with process lineage (e.g., Python, bash, or unusual system daemons).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0110 - AN0110"*

Table 5881. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0039#AN0110

Analytic 0101 - AN0101

Non-interactive system processes making encrypted HTTPS connections to well-known web services followed by high outbound traffic volume or scripted upload patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0101 - AN0101"*

Table 5882. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0035#AN0101

Analytic 1001 - AN1001

Registry modifications to HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Winlogon\SpecialAccounts\UserList setting user visibility to 0, or creation of user accounts not shown on login screen. Defender view: correlation of account creation with registry edits that mark users hidden.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1001 - AN1001"*

Table 5883. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0353#AN1001

Analytic 1010 - AN1010

Detect abnormal use of email clients (e.g., Outlook, Thunderbird) showing mass arrival of messages or repetitive attachments being locally stored. Correlate message volume with file creation activity in mail cache directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1010 - AN1010"*

Table 5884. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0355#AN1010

Analytic 0011 - AN0011

Modification of PATH or HOME environment variables through shell config files, launchctl, or /etc/paths.d entries, combined with process execution from attacker-controlled directories. Defender correlates file changes in /etc/paths.d with process execution resolving to malicious binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0011 - AN0011"*

Table 5885. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0004#AN0011

Analytic 1100 - AN1100

Adversary spawns a process or script to enumerate installed software using WMI, registry, or PowerShell, potentially followed by additional discovery or evasion behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1100 - AN1100"*

Table 5886. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0392#AN1100

Analytic 1020 - AN1020

Suspicious processes (e.g., Tor clients, relays, unknown binaries) launch with sustained encrypted outbound traffic to known anonymity infrastructure (e.g., Tor, I2P), and may relay to additional internal systems via reverse proxying, ICMP tunneling, or socket forwarding.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1020 - AN1020"*

Table 5887. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0359#AN1020

Analytic 1200 - AN1200

Monitors Keychain database access and suspicious invocations of security and osascript utilities. Correlates process execution with attempts to dump or unlock Keychain data.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1200 - AN1200"*

Table 5888. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0430#AN1200

Analytic 1002 - AN1002

Use of gsettings or direct Display Manager modifications to hide users from greeter login screen. Defender view: anomalous command execution modifying org.gnome.login-screen or other greeter configurations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1002 - AN1002"*

Table 5889. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0353#AN1002

Analytic 0102 - AN0102

Scripting engines (e.g., osascript, Python) initiating HTTPS requests to social media or content-sharing platforms, paired with automated response handling indicative of two-way communication.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0102 - AN0102"*

Table 5890. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0035#AN0102

Analytic 0210 - AN0210

Detects embedded or emulated VBScript/VBA execution via Wine-based apps, Office for Mac abusing cross-platform .NET features, or macros dropped and invoked via AppleScript or third-party automation tools.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0210 - AN0210"*

Table 5891. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0076#AN0210

Analytic 0201 - AN0201

Anomalous access to cloud web applications using session tokens without corresponding MFA/credential validation, often from unusual locations or device fingerprints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0201 - AN0201"*

Table 5892. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0074#AN0201

Analytic 2010 - AN2010

Monitor for suspicious email activity, such as numerous accounts receiving messages from a single unusual/unknown sender. Filtering based on DKIM+SPF or header analysis can help detect when the email sender is spoofed.(Citation: Microsoft Anti Spoofing)(Citation: ACSC Email Spoofing) Monitor for references to uncategorized or known-bad sites. URL inspection within email (including expanding shortened links and identifying obfuscated URLs) can also help detect links leading to known malicious sites.(Citation: Mandiant URL Obfuscation 2023)

Furthermore, monitor browser logs for homographs in ASCII and in internationalized domain names abusing different character sets (e.g. Cyrillic vs Latin versions of trusted sites). Monitor network data for uncommon data flows. Processes utilizing the network that do not normally have network communication or have never been seen before are suspicious. Monitor and analyze traffic patterns and packet inspection associated to protocol(s), leveraging SSL/TLS inspection for encrypted traffic, that do not follow the expected protocol standards and traffic flows (e.g extraneous packets that do not belong to established flows, gratuitous or anomalous traffic patterns, anomalous syntax, or structure). Consider correlation with process monitoring and command line to detect anomalous processes execution and command line arguments associated to traffic patterns (e.g. monitor anomalies in use of files that do not normally initiate connections for respective protocol(s)).

Furthermore, monitor network traffic for homographs via the use of internationalized domain names abusing different character sets (e.g. Cyrillic vs Latin versions of trusted sites). Also monitor and analyze traffic patterns and packet inspection for indicators of cloned websites. For example, if adversaries use HTTrack to clone websites, <code> Mirrored from (victim URL)</code> may be visible in the HTML section of packets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2010 - AN2010"*

Analytic 0021 - AN0021

Adversary manipulates dependencies/dev tools used by developers or CI: a package manager (npm/yarn/pnpm, pip/pipenv, nuget/dotnet, chocolatey/winget, maven/gradle) or a compiler/IDE downloads or restores content; files are written under project paths and execution paths (node_modules, packages, .nuget, .gradle, .m2, %AppData%\npm, %UserProfile%\.cargo\bin, temp build dirs). First run of newly written components triggers scripts (preinstall/postinstall), shell/PowerShell spawning, or loader DLLs, followed by network egress to non-approved registries/CDNs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0021 - AN0021"*

Table 5894. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0009#AN0021

Analytic 2001 - AN2001

Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders.

Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2001 - AN2001"*

Table 5895. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0869#AN2001

Analytic 0120 - AN0120

Detection of commands accessing locale, timezone, or language settings such as 'locale', 'timedatectl', or parsing /etc/timezone. Anomalous execution by unusual users or automation scripts should be flagged.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0120 - AN0120"*

Table 5896. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0043#AN0120

Analytic 0012 - AN0012

Execution of binaries where the on-disk filename does not match PE metadata such as OriginalFilename or InternalName. Often observed with renamed LOLBAS or system binaries like rundll32, powershell, or psexec.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0012 - AN0012"*

Table 5897. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0005#AN0012

Analytic 0103 - AN0103

Adversary registers new devices to compromised user accounts to bypass MFA or conditional access policies via Azure Entra ID, Okta, or Duo self-enrollment portals.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0103 - AN0103"*

Table 5898. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0036#AN0103

Analytic 0130 - AN0130

Detection focuses on processes that attempt to locate, access, or exfiltrate local Outlook data files (.pst/.ost) using file system access, native Windows utilities (e.g., PowerShell, WMI), or remote access tools with file browsing capabilities. The behavior chain includes directory enumeration, file access, optional compression or staging, and network transfer.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0130 - AN0130"*

Table 5899. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0047#AN0130

Analytic 1030 - AN1030

A non-privileged or abnormal process attempts to open a handle with full access (0x1F0FFF) to lsass.exe and subsequently invokes memory dump, file creation, or registry modification indicative of credential scraping. This behavior chain reflects staged credential theft activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1030 - AN1030"*

Table 5900. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0363#AN1030

Analytic 0013 - AN0013

Execution of renamed or relocated native macOS utilities with uncommon names or non-default paths (e.g., renamed `osascript`, `bash`, or `curl`).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0013 - AN0013"*

Table 5901. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0005#AN0013

Analytic 1300 - AN1300

Detects modification of shared network folders via .app bundles or scripting files with hidden extensions (e.g., double extensions like docx.app).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1300 - AN1300"*

Table 5902. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0471#AN1300

Analytic 0031 - AN0031

Outbound traffic with anomalous payload sizes and patterns from non-networking processes, often observed via packet inspection or connection logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0031 - AN0031"*

Table 5903. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0011#AN0031

Analytic 0310 - AN0310

Detection monitors SaaS collaboration tools (e.g., Slack, Zoom, Jira) for messages or files containing credential-like patterns, or for suspicious API calls retrieving bulk chat histories by non-admin users. Identifies adversary behavior chains where chat logs are queried via APIs or integration bots to systematically extract sensitive material.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0310 - AN0310"*

Table 5904. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0111#AN0310

Analytic 1003 - AN1003

User creation or modification via dscl with IsHidden=1, UID<500, or plist edits to com.apple.loginwindow Hide500Users flag. Defender view: correlation of hidden account attributes with login screen exclusion.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1003 - AN1003"*

Table 5905. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0353#AN1003

Analytic 0301 - AN0301

Detection of OAuth consent phishing or malicious login attempts initiated through spearphishing links. Behavior chain includes inbound email with OAuth URL → consent page visited → unusual token grants logged in IdP logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0301 - AN0301"*

Table 5906. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0107#AN0301

Analytic 0410 - AN0410

Detection of firewall ACL or rule base changes through CLI (e.g., no access-list, permit any any). Monitor configuration commits from unusual users or sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0410 - AN0410"*

Table 5907. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0145#AN0410

Analytic 1400 - AN1400

Detects ptrace- or memfd-based process injection through audit logs capturing system calls (e.g., ptrace, mmap) targeting running processes along with suspicious file descriptors or memory writes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1400 - AN1400"*

Table 5908. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0508#AN1400

Analytic 1004 - AN1004

Unusual or unauthorized external remote access attempts (e.g., RDP, VPN, Citrix) → repeated failed logins followed by a successful session from uncommon geolocations or outside business hours → subsequent internal lateral movement or data exfiltration activities.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1004 - AN1004"*

Table 5909. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0354#AN1004

Analytic 1040 - AN1040

Execution of file enumeration commands (e.g., 'dir', 'tree') from non-standard processes or unusual user contexts, followed by recursive directory traversal or access to sensitive locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1040 - AN1040"*

Table 5910. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0370#AN1040

Analytic 0401 - AN0401

Unexpected processes (e.g., bash, python, custom binaries) dynamically loading libcrypto or performing AES/RC4 encryption operations, then initiating outbound sessions with abnormal byte entropy or asymmetric traffic patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0401 - AN0401"*

Table 5911. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0143#AN0401

Analytic 0014 - AN0014

Execution of renamed common utilities (e.g., `bash`, `nc`, `python`, `sh`) from atypical directories or with names intended to deceive defenders or EDRs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0014 - AN0014"*

Table 5912. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0005#AN0014

Analytic 0104 - AN0104

Adversary registers a Windows device to Entra ID or bypasses conditional access by adding device via Intune registration pipeline using stolen credentials.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0104 - AN0104"*

Table 5913. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0036#AN0104

Analytic 0041 - AN0041

Detects script or user activity copying files to a central temp or /mnt directory followed by archive/compression utilities.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0041 - AN0041"*

Table 5914. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0014#AN0041

Analytic 0140 - AN0140

Adversaries writing or moving payloads into directories configured as AV/EDR exclusion paths (e.g., /tmp, /var/lib, or custom directories from auditd exclusion rules). Defender perspective: detect file creation in paths matching known exclusions correlated with unusual parent processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0140 - AN0140"*

Table 5915. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0051#AN0140

Analytic 0150 - AN0150

Internal spearphishing via SaaS applications (e.g., Slack, Teams, Gmail): message sent from compromised user with attachment or URL, followed by click and credential access behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0150 - AN0150"*

Table 5916. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0054#AN0150

Analytic 0501 - AN0501

Post-compromise identity & session anomalies that follow a drive-by compromise: token reuse from new/unfamiliar IPs, anomalous sign-in patterns for previously inactive users, unexpected consent/grant events, or provisioning changes. Defender sees an endpoint/browser compromise (network + endpoint signals) followed by unusual IdP events: new refresh token issuance, consent/consent-grant events, odd MFA bypass patterns, or unusual OAuth client registrations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0501 - AN0501"*

Table 5917. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0176#AN0501

Analytic 0015 - AN0015

From a defender's perspective, suspicious bridging is observed when network devices begin allowing traffic that contradicts existing segmentation or access policies. Observable behaviors include sudden modifications to ACLs or firewall rules, unusual cross-boundary traffic flows (e.g., east-west communications across separated VLANs), or simultaneous ingress/egress anomalies. Multi-event correlation is key: configuration changes on a router/firewall followed by unexpected traffic patterns, especially from unusual sources, is a strong indicator of compromise.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0015 - AN0015"*

Table 5918. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0006#AN0015

Analytic 1500 - AN1500

Encrypted sessions detected with asymmetric key exchange anomalies on non-standard ports or with invalid/malformed certs. Defender correlates NetFlow/IPFIX with IDS/IPS detecting RSA exchanges outside expected TLS flows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1500 - AN1500"*

Table 5919. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0543#AN1500

Analytic 0510 - AN0510

Detection correlates file creation or modification of `.lnk` (shortcut) files in autostart locations with anomalous parent-child process lineage or unsigned binaries. Defenders should watch for LNK creation/modification events outside of known software installations, patch events, or OS updates. Flag shortcut targets pointing to suspicious locations or unknown binaries, particularly those written by script interpreters or spawned from phishing delivery chains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0510 - AN0510"*

Table 5920. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0180#AN0510

Analytic 0051 - AN0051

Correlated modification of AppCompat registry keys and execution of sdbinst.exe to install custom shim databases. Followed by DLL injection via shim behavior into target application processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0051 - AN0051"*

Table 5921. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0017#AN0051

Analytic 1050 - AN1050

Execution of AppleScript, bash, or launchd jobs that invoke delay functions (e.g., sleep, delay in AppleScript) with limited parent interaction and staged follow-on commands.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1050 - AN1050"*

Table 5922. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0372#AN1050

Analytic 1005 - AN1005

Repeated SSH, VPN, or RDP gateway authentication attempts from external IPs → subsequent successful logon → remote shell or lateral movement activity (e.g., scp/sftp).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1005 - AN1005"*

Table 5923. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0354#AN1005

Analytic 0105 - AN0105

Detects unauthorized access to web browser credential stores (e.g., Chrome Login Data, Edge Credential Locker) by processes other than the browser itself. Correlates file reads of credential databases with subsequent API calls to `CryptUnprotectData` or memory inspection attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0105 - AN0105"*

Table 5924. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0037#AN0105

Analytic 0061 - AN0061

Adversary disables or stops critical services (e.g., Exchange, SQL, AV, endpoint monitoring) using native utilities or API calls, often preceding destructive actions (T1485, T1486). Behavioral chain: Elevated execution context + stop-service or sc.exe or ChangeServiceConfigW + terminated or disabled service + possible follow-up file manipulation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0061 - AN0061"*

Table 5925. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0021#AN0061

Analytic 1006 - AN1006

Unexpected inbound or outbound VNC/SSH/Screen Sharing connections from external sources → repeated failed logins followed by success → remote interactive sessions or abnormal file transfers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1006 - AN1006"*

Table 5926. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0354#AN1006

Analytic 1060 - AN1060

Detects lateral discovery or container breakout attempts using netcat, curl, or custom binaries probing other services within the same namespace or VPC subnet.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1060 - AN1060"*

Table 5927. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0376#AN1060

Analytic 0160 - AN0160

Detection of a process or script that accesses a common web service to retrieve content containing obfuscated indicators of a secondary C2 server (dead drop resolver behavior).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0160 - AN0160"*

Table 5928. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0058#AN0160

Analytic 0601 - AN0601

Detection of Mach-O binaries or AppleScripts that contain nested, encoded, or run-only embedded payloads dropped at runtime.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0601 - AN0601"*

Table 5929. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0214#AN0601

Analytic 0016 - AN0016

Adversary uses nltest, PowerShell, or Win32/.NET API to enumerate domain trust relationships (via DSEnumerateDomainTrusts, GetAllTrustRelationships, or LDAP queries), followed by discovery or authentication staging.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0016 - AN0016"*

Table 5930. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0007#AN0016

Analytic 0106 - AN0106

Detects attempts to access browser credential stores (e.g., Firefox `logins.json`, Chrome SQLite DB) or processes (e.g., gnome-keyring-daemon). Observes unauthorized file reads and memory inspection of browser processes using ptrace or gdb.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0106 - AN0106"*

Table 5931. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0037#AN0106

Analytic 0610 - AN0610

Adversary manipulation of shared library paths, environment variables, or replacement of service binaries. Defender observes suspicious modifications in /etc/ld.so.preload, service config changes, or file writes replacing existing executables.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0610 - AN0610"*

Table 5932. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0218#AN0610

Analytic 1600 - AN1600

Curl, wget, or custom HTTP clients initiated by uncommon user accounts or cron jobs to popular web services, with no observed response parsing logic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1600 - AN1600"*

Table 5933. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0581#AN1600

Analytic 1007 - AN1007

Connections to exposed container services (e.g., Docker API, Kubernetes API server) from unauthorized external IPs → abnormal container creation/start → lateral activity within cluster nodes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1007 - AN1007"*

Table 5934. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0354#AN1007

Analytic 0107 - AN0107

Detects abnormal access to Safari credential stores (Keychain-backed) or Chrome/Firefox login databases. Observes processes executing `security dump-keychain` or directly reading credential files in `~/Library/Application Support`. Correlates file access with suspicious process ancestry or unsigned binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0107 - AN0107"*

Table 5935. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0037#AN0107

Analytic 0710 - AN0710

Suspicious reuse of SSH agent sockets across multiple users or processes, anomalous access to ~/.ssh/ or /tmp/ssh-* sockets, and abnormal patterns of lateral movement via SSH without new authentication events. Defender view: detect when one process accesses another user's SSH agent or when an existing SSH connection is used to pivot unexpectedly.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0710 - AN0710"*

Table 5936. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0256#AN0710

Analytic 0170 - AN0170

Detects modification of registry keys used for default file handlers, followed by anomalous process execution from user-initiated file opens. This includes tracking changes under HKCU and HKCR for file extension mappings, and correlating them with new or suspicious handler paths launching unusual child processes (e.g., PowerShell, cmd, wscript).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0170 - AN0170"*

Table 5937. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0061#AN0170

Analytic 0701 - AN0701

Detects the creation or modification of `.service` unit files in system/user-level directories, combined with execution of `systemctl`, `service`, or dynamically created drop-ins via systemd generators. Detects persistence by analyzing the `ExecStart` path, file entropy, and symlink usage, especially when paired with execution from `/tmp`, `/dev/shm`, or unmounted volumes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0701 - AN0701"*

Table 5938. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0253#AN0701

Analytic 1070 - AN1070

Adversaries collecting local files via PowerShell, WMI, or direct file API calls often include recursive file listings, targeted file reads, and temporary file staging.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1070 - AN1070"*

Table 5939. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0380#AN1070

Analytic 0017 - AN0017

Cloud login from atypical geolocation or user-agent string, followed by resource enumeration or infrastructure manipulation using cloud CLI/API

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0017 - AN0017"*

Table 5940. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0008#AN0017

Analytic 0071 - AN0071

Abuse of trusted Electron apps (Teams, Slack, Chrome) to spawn child processes or execute payloads via malicious command-line arguments (e.g., --gpu-launcher) and modified app resources (.asar). Behavior chain: suspicious parent process (Electron app) → unusual command-line args → child process creation → optional DLL/network artifacts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0071 - AN0071"*

Table 5941. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0025#AN0071

Analytic 1700 - AN1700

Network traffic analysis may reveal processes communicating with malicious domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1700 - AN1700"*

Table 5942. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0629#AN1700

Analytic 0081 - AN0081

User-initiated processes generating sustained outbound traffic over common or non-standard ports, often outside business hours, potentially linked to scanning or proxyjacking. Includes curl, wget, masscan, or proxy clients.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0081 - AN0081"*

Table 5943. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0028#AN0081

Analytic 1008 - AN1008

Detect abnormally high volume of inbound email messages or repetitive attachments being delivered to a single mailbox within a short time window. Defenders should look for anomalous spikes in message counts and repetitive attachment file creation events correlated with targeted users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1008 - AN1008"*

Table 5944. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0355#AN1008

Analytic 0180 - AN0180

Behavioral chain: (1) Safari/Chrome/Firefox/Office handles a URL; unified logs show open/click or LSQuarantine assignment, (2) outbound connection to untrusted domain, (3) a new file appears in ~/Downloads or /private/var/folders/* with quarantine flag.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0180 - AN0180"*

Table 5945. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0066#AN0180

Analytic 0108 - AN0108

Executables written or modified in installer directories (e.g., %TEMP% subdirectories or Program Files installer paths) followed by execution under elevated context. Defender observes abnormal file replacement activity, process creation by installer processes pointing to attacker-supplied binaries, and unexpected module loads in elevated processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0108 - AN0108"*

Table 5946. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0038#AN0108

Analytic 0810 - AN0810

Detects login to admin consoles (e.g., Microsoft 365 Admin Center) from unrecognized users, devices, or geolocations followed by non-API data review or configuration read actions that suggest GUI dashboard use.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0810 - AN0810"*

Table 5947. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0291#AN0810

Analytic 0801 - AN0801

Cloud API events where logging services are stopped, deleted, or modified in a way that disables audit visibility. Defender view: unauthorized StopLogging, DeleteTrail, or UpdateSink operations correlated with privileged user activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0801 - AN0801"*

Table 5948. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0289#AN0801

Analytic 0018 - AN0018

Federated login using SSO or OAuth grant to cloud control plane, followed by directory or permissions enumeration

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0018 - AN0018"*

Table 5949. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0008#AN0018

Analytic 1080 - AN1080

Monitors for the creation of accounts inside containers using names that resemble legitimate orchestrator or backup identities to mask adversary persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1080 - AN1080"*

Table 5950. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0383#AN1080

Analytic 1090 - AN1090

Access to organizational directories via Google Workspace Directory API, Slack SCIM, or Okta SCIM by apps or identities outside normal roles.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1090 - AN1090"*

Table 5952. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0386#AN1090

Analytic 0190 - AN0190

Detection of phishing through anomalous Mail app activity, such as attachments saved to disk and immediately executed, or Safari/Preview launching URLs and files linked from email messages. Correlate UnifiedLogs events with subsequent process execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0190 - AN0190"*

Table 5953. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0070#AN0190

Analytic 1009 - AN1009

Monitor mail server logs (e.g., Postfix, Sendmail) for excessive connections or inbound message counts targeting a single recipient. Correlate with repetitive attachment storage in /var/mail or /var/spool/mail directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1009 - AN1009"*

Table 5954. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0355#AN1009

Analytic 0091 - AN0091

Suspicious use of attrib.exe or PowerShell commands to set hidden attributes on files/directories. Defender view: processes modifying file attributes to 'hidden' or creating files with ADS (alternate data streams).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0091 - AN0091"*

Table 5955. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0032#AN0091

Analytic 0910 - AN0910

Execution of QEMU, KVM, or VirtualBox processes with unusual flags (e.g., '-nographic', '-snapshot'). File creation of VM images in atypical directories. Defender view: monitoring audit logs for process executions and file modifications linked to hidden virtualization.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0910 - AN0910"*

Table 5956. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0321#AN0910

Analytic 0109 - AN0109

Correlate high-frequency or anomalous DNS query activity with processes that do not normally generate network requests (e.g., Office apps, system utilities). Detect pseudo-random or high-entropy domain lookups indicative of domain generation algorithms (DGAs).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0109 - AN0109"*

Table 5957. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0039#AN0109

Analytic 0019 - AN0019

Login to M365 or Google Workspace from CLI tools or unexpected source IPs, followed by mailbox or document access

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0019 - AN0019"*

Table 5958. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0008#AN0019

Analytic 0901 - AN0901

Adversaries create SaaS accounts via admin dashboards or integrations (e.g., Zoom, Salesforce, Slack). Monitor lifecycle.create or account provisioning events from non-standard sources or times.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0901 - AN0901"*

Table 5959. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0319#AN0901

Analytic 0202 - AN0202

Session cookie reuse on unmanaged browsers, devices, or client types deviating from user baseline (e.g., switching from Chrome to curl).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0202 - AN0202"*

Table 5960. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0074#AN0202

Analytic 2002 - AN2002

Consider monitoring social media activity related to your organization. Suspicious activity may include personas claiming to work for your organization or recently modified accounts making numerous connection requests to accounts affiliated with your organization. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access (ex: [Spearphishing via Service](https://attack.mitre.org/techniques/T1566/003)). Monitor and analyze traffic patterns and packet inspection associated to protocol(s), leveraging SSL/TLS inspection for encrypted traffic, that do not follow the expected protocol standards and traffic flows (e.g extraneous packets that do not belong to established flows, gratuitous or anomalous traffic patterns, anomalous syntax, or structure). Consider correlation with process monitoring and command line to detect anomalous processes execution and command line arguments associated to traffic patterns (e.g. monitor anomalies in use of files that do not normally initiate connections for respective protocol(s)).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2002 - AN2002"*

Table 5961. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0870#AN2002

Analytic 0022 - AN0022

Developer or CI invokes package managers/compilers (apt/yum + build-essential, npm/yarn/pnpm, pip/pip3, gem, cargo, go, maven/gradle). These write executable or script files into PATH or project dirs and immediately execute embedded lifecycle hooks (preinstall/postinstall, setup.py, npm scripts) that spawn shells or curl/wget, followed by egress to unfamiliar registries or domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0022 - AN0022"*

Table 5962. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0009#AN0022

Analytic 0220 - AN0220

Adversary exploits Apache/Nginx/app servers. Chain: (1) suspicious requests in access logs → (2) spike of 5xx or WAF blocks → (3) web server or interpreter (apache2/nginx/php-fpm/node/python) spawns /bin/sh, curl, wget, socat, or writes webshell → (4) outbound callback.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0220 - AN0220"*

Table 5963. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0080#AN0220

Analytic 2020 - AN2020

Internet scanners may be used to look for patterns associated with malicious content designed to collect host software information from visitors.(Citation: ThreatConnect Infrastructure Dec 2020)(Citation: ATT ScanBox) Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2020 - AN2020"*

Analytic 0230 - AN0230

Adversary leverages root or sudo access to alter system banners, web content directories (e.g., /var/www/html), or login configurations (/etc/issue). File creation or overwrites may coincide with suspicious script execution or cron job activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0230 - AN0230"*

Table 5970. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0082#AN0230

Analytic 0320 - AN0320

Inbound spearphishing attempts delivered via third-party services (e.g., Gmail, LinkedIn messages) leading to malicious file downloads or browser-initiated script execution. Defender view includes correlation of external service logins, unexpected file write operations, and suspicious descendant processes spawned from productivity or browser applications.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0320 - AN0320"*

Table 5971. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0115#AN0320

Analytic 0302 - AN0302

Atypical processes (e.g., powershell.exe, regsvr32.exe) encode large outbound traffic using Base64 or other character encodings; this traffic is sent over uncommon ports or embedded in protocol fields (e.g., HTTP cookies or headers).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0302 - AN0302"*

Table 5972. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0108#AN0302

Analytic 2004 - AN2004

Consider analyzing malware for features that may be associated with the adversary and/or their developers, such as compiler used, debugging artifacts, or code similarities. Malware repositories can also be used to identify additional samples associated with the adversary and identify development patterns over time. Monitor for contextual data about a malicious payload, such as compilation times, file hashes, as well as watermarks or other identifiable configuration information. Much of this activity will take place outside the visibility of the target organization, making detection of this behavior difficult. Detection efforts may be focused on post-compromise phases of the adversary lifecycle.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2004 - AN2004"*

Table 5973. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0872#AN2004

Analytic 0042 - AN0042

Detects files collected into user temp or shared directories followed by compression with ditto, zip,

or custom scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0042 - AN0042"*

Table 5974. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0014#AN0042

Analytic 0402 - AN0402

Launchd jobs or user processes invoking symmetric crypto APIs from the Security framework and generating outbound connections carrying randomized payloads inconsistent with normal TLS patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0402 - AN0402"*

Table 5975. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0143#AN0402

Analytic 0420 - AN0420

Forged SAML tokens may be used on Windows systems to authenticate to federated apps without normal Kerberos activity. Defenders may detect anomalous event correlation, where access to SaaS/O365 via SAML occurs without prior TGT requests or user logons.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0420 - AN0420"*

Table 5976. Table References

Analytic 2008 - AN2008

Consider monitoring social media activity related to your organization. Suspicious activity may include personas claiming to work for your organization or recently modified accounts making numerous connection requests to accounts affiliated with your organization. Much of this activity will take place outside the visibility of the target organization, making detection of this behavior difficult. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access (ex: [Phishing](https://attack.mitre.org/techniques/T1566)). Monitor and analyze traffic patterns and packet inspection associated to protocol(s) that do not follow the expected protocol standards and traffic flows (e.g extraneous packets that do not belong to established flows, gratuitous or anomalous traffic patterns, anomalous syntax, or structure). Consider correlation with process monitoring and command line to detect anomalous processes execution and command line arguments associated to traffic patterns (e.g. monitor anomalies in use of files that do not normally initiate connections for respective protocol(s)).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2008 - AN2008"*

Table 6003. Table References

Analytic 0830 - AN0830

Execution of destructive CLI commands such as format flash:, format disk, or equivalent vendor-specific commands that erase filesystem structures. Detection correlates AAA logs showing privileged access with immediate format/erase commands.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0830 - AN0830"*

Table 6046. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0297#AN0830

Analytic 0803 - AN0803

Disabling mailbox or tenant-level audit logging, often using Set-MailboxAuditBypassAssociation or downgrading license tiers. Defender view: sudden absence of mailbox activity logging for monitored users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0803 - AN0803"*

Table 6047. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0289#AN0803

Analytic 0039 - AN0039

Scripting or CLI tool access to ~/Library/Application Support/Google/Chrome or ~/Library/Safari bookmarks, cookies, or history databases. Detection relies on unexpected processes accessing or reading from these locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0039 - AN0039"*

Table 6048. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0013#AN0039

Analytic 0309 - AN0309

Detection correlates message events in email and collaboration tools (e.g., Outlook, Teams) that contain regex-like patterns resembling credentials, API keys, or tokens. Anomalous forwarding or bulk copy activity of chat/email content containing secrets is flagged. Suspicious behavior includes users pasting secrets into direct messages or attaching config files with passwords.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0309 - AN0309"*

Table 6049. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0111#AN0309

Analytic 0093 - AN0093

Use of chflags hidden or SetFile -a V commands to hide files, or creation of hidden files with leading '.'. Defender view: monitoring process execution and file metadata changes setting UF_HIDDEN

attribute.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0093 - AN0093"*

Table 6050. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0032#AN0093

Analytic 0390 - AN0390

Detects credential interception via malicious LD_PRELOAD-based shared libraries loaded into ssh, sudo, or scp processes. Correlates environment variable injection, unexpected library loads, and memory patching behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0390 - AN0390"*

Table 6051. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0139#AN0390

Analytic 0903 - AN0903

Detects usage of commands or binaries (e.g., netstat, PowerShell Get-NetTCPConnection) and WMI or API calls to enumerate local or remote network connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0903 - AN0903"*

Table 6052. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0903

Analytic 0930 - AN0930

ESXi shell or scripts produce long, high-entropy tokens (non-standard alphabets) in shell.log/hostd, followed by outbound flows (NSX/Zeek) with asymmetric ratios or protocol mismatches to non-management endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0930 - AN0930"*

Table 6053. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0326#AN0930

Analytic 0440 - AN0440

Suspicious SaaS tenant activity involving webhook configurations pointing to external or untrusted domains. Defender perspective: repeated automated exports or suspicious webhook endpoint registrations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0440 - AN0440"*

Table 6054. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0153#AN0440

Analytic 0404 - AN0404

Flows showing encrypted payloads with high entropy not matching TLS handshake patterns, particularly when occurring on non-standard ports. Defender observes NetFlow/IPFIX byte distribution anomalies or IDS/IPS detecting symmetric encryption patterns without associated key exchange.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0404 - AN0404"*

Table 6055. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0143#AN0404

Analytic 0044 - AN0044

Detects snapshots or data stored in VMFS volumes from root CLI or remote agents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0044 - AN0044"*

Table 6056. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0014#AN0044

Analytic 0045 - AN0045

Detects unusual command executions and service modifications that indicate self-patching or disabling of vulnerable services post-compromise. Defenders should monitor for service stop commands, suspicious process termination, and execution of binaries or scripts aligned with known patching or service management tools outside of expected admin contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0045 - AN0045"*

Table 6057. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0015#AN0045

Analytic 0540 - AN0540

Detection of known tools or malware flagged by antivirus, followed by a near-term drop of a similar binary with modified signature and resumed activity (execution, C2, or persistence).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0540 - AN0540"*

Table 6058. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0189#AN0540

Analytic 0054 - AN0054

A process loads a non-system .dylib/.so via dyld (dlopen/dlsym) from user-writable locations (~/Library, /tmp) or after the library was recently created/downloaded, often followed by network egress or persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0054 - AN0054"*

Table 6059. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0018#AN0054

Analytic 0504 - AN0504

Detection of VNC service or executable starting unexpectedly, followed by user session creation and interactive desktop activity (mouse/keyboard simulation).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0504 - AN0504"*

Table 6060. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0178#AN0504

Analytic 0450 - AN0450

Detect abnormal MFA activity within cloud service provider logs, such as repeated generation of MFA challenges for the same user session or mismatched MFA device and login origin.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0450 - AN0450"*

Table 6061. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0160#AN0450

Analytic 0405 - AN0405

Detects forged Kerberos Golden Tickets by correlating anomalous Kerberos ticket lifetimes, unexpected encryption types (e.g., RC4 in modern domains), malformed fields in logon/logoff events, and TGS requests without preceding TGT requests. Also monitors for abnormal patterns of access associated with elevated privileges across multiple systems.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0405 - AN0405"*

Table 6062. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0144#AN0405

Analytic 0046 - AN0046

Detects adversary attempts to monopolize control of compromised systems by issuing service stop commands, unloading vulnerable modules, or forcefully killing competing processes. Defenders should monitor audit logs and syslog for administrative utilities (systemctl, service, kill) being invoked outside of normal change management.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0046 - AN0046"*

Table 6063. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0015#AN0046

Analytic 0604 - AN0604

Userland or kernel-level ransomware encrypting user files (Documents, Desktop) using `srm`, `gpg`, or compiled payloads. Often correlated with ransom note creation in multiple directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0604 - AN0604"*

Table 6064. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0215#AN0604

Analytic 0064 - AN0064

Attacker disables VM-related services or stops VMs forcibly to target vmdk or logs. Behavioral chain: esxcli or vim-cmd stop + audit log showing user privilege use + datastore file manipulation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0064 - AN0064"*

Table 6065. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0021#AN0064

Analytic 0460 - AN0460

Chain: (1) SaaS admin API or PowerShell remote session reads tenant password/authentication settings (e.g., M365 Unified Audit Log 'Cmdlet' with `Get-MsolPasswordPolicy`/`Get-OrganizationConfig` parameters that expose password settings); (2) same session proceeds to mailbox or tenant changes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0460 - AN0460"*

Table 6066. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0161#AN0460

Analytic 0406 - AN0406

Detection of firewall tampering by monitoring processes executing netsh, PowerShell Set-NetFirewallProfile, or sc stop mpssvc. Registry modifications under HKLM\SYSTEM\CurrentControlSet\Services\SharedAccess\Parameters\FirewallPolicy also indicate adversarial actions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0406 - AN0406"*

Table 6067. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0145#AN0406

Analytic 0640 - AN0640

CLI-based or API-based network call from the hypervisor to external staging host, shortly followed by a connection to a second external IP by a spawned process or scheduled task.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0640 - AN0640"*

Table 6068. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0228#AN0640

Analytic 0407 - AN0407

Detection of iptables, nftables, or firewalld rule modifications. Correlation of sudden drops in active firewall rules with suspicious processes suggests adversarial evasion.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0407 - AN0407"*

Table 6069. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0145#AN0407

Analytic 0470 - AN0470

Detects modification or truncation of `/var/log/shell.log` used to persist ESXi shell command history. Especially suspicious shortly after login or config changes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0470 - AN0470"*

Table 6070. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0165#AN0470

Analytic 0704 - AN0704

Monitor system APIs such as CFNetwork and SecureTransport for anomalies in transmitted data streams. Detect mismatches in file hashes or SSL/TLS downgrade attempts that enable manipulation of transmitted data.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0704 - AN0704"*

Table 6071. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0254#AN0704

Analytic 0740 - AN0740

Detects Exchange Online or on-prem transport rule changes (e.g., header stripping) and mailbox export cleanup via `Remove-MailboxExportRequest`, as well as admin actions via Exchange PowerShell sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0740 - AN0740"*

Table 6072. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0266#AN0740

Analytic 0047 - AN0047

Detects unauthorized termination of system daemons or commands issued through launchctl or kill to stop competing services or malware processes. Defenders should monitor unified logs and EDR telemetry for unusual service modifications or terminations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0047 - AN0047"*

Table 6073. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0015#AN0047

Analytic 0074 - AN0074

Correlated registry modifications under Print Processors path, followed by DLL file creation within the system print processor directory, and DLL load by spoolsv.exe. Malicious execution often occurs during service restart or system boot, with SYSTEM-level privileges.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0074 - AN0074"*

Table 6074. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0026#AN0074

Analytic 0408 - AN0408

Detection of PF firewall rule modifications via pfctl, socketfilterfw, or defaults write to com.apple.alf. Adversaries often disable firewall profiles entirely or whitelist malicious processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0408 - AN0408"*

Table 6075. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0145#AN0408

Analytic 0480 - AN0480

Bash, Swift, or Objective-C programs enumerate system profile, I/O registry, or inspect kernel extensions to identify VM artifacts

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0480 - AN0480"*

Table 6076. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0168#AN0480

Analytic 0804 - AN0804

Disabling or altering security and audit logs in SaaS admin panels (e.g., Slack, Zoom, Salesforce). Defender view: API calls or admin console changes that stop event exports or logging integrations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0804 - AN0804"*

Table 6077. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0289#AN0804

Analytic 0084 - AN0084

Virtual instances or workloads generating sustained outbound data rates, often to TOR, VPN, or proxy endpoints. Often coincides with unusual IAM usage or deployed scripts (e.g., cron jobs using proxy clients).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0084 - AN0084"*

Table 6078. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0028#AN0084

Analytic 0048 - AN0048

Adversary executes commands to enumerate installed antivirus, EDR, or firewall agents using WMI, registry queries, and built-in tools (e.g., tasklist, netsh, sc query). Correlated with elevated process privileges or scripting engine usage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0048 - AN0048"*

Table 6079. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0016#AN0048

Analytic 0840 - AN0840

Suspicious calls to dlopen(), dlsym(), or mmap with RWX flags in processes that do not typically perform dynamic module loading. Monitor anonymous memory regions executed by user processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0840 - AN0840"*

Table 6080. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0300#AN0840

Analytic 0904 - AN0904

Detects use of netstat, ss, lsof, or custom shell scripts to list current network connections. Often paired with privilege escalation or staging.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0904 - AN0904"*

Table 6081. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0904

Analytic 0409 - AN0409

Detection of firewall changes using esxcli network firewall set or vSphere API modifications. Sudden disabling of firewall rules across management interfaces is a strong adversarial signal.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0409 - AN0409"*

Table 6082. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0145#AN0409

Analytic 0049 - AN0049

Adversary runs discovery commands such as `ps aux`, `systemctl status`, or `cat /etc/init.d/` to enumerate security software or services. Often occurs alongside privilege escalation or bash script execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0049 - AN0049"*

Table 6083. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0016#AN0049

Analytic 0094 - AN0094

Defenders can observe suspicious replacement or tampering of system accessibility binaries (e.g., utilman.exe, sethc.exe, osk.exe) and anomalous modifications to registry keys used to redirect

accessibility programs (such as IFEO keys). Additionally, execution of cmd.exe or other suspicious binaries triggered from the login screen by SYSTEM can be correlated as part of a behavior chain.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0094 - AN0094"*

Table 6084. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0033#AN0094

Analytic 0940 - AN0940

Detection of msiexec.exe running installer packages that result in anomalous process creation. Look for unexpected binaries executed by msiexec or custom action DLLs in the temp directory.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0940 - AN0940"*

Table 6085. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0330#AN0940

Analytic 0490 - AN0490

Excessive inbound HTTP or TLS connections to services such as Apache or Nginx, causing worker thread exhaustion or segmentation faults.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0490 - AN0490"*

Table 6086. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0173#AN0490

Analytic 0505 - AN0505

Spawning of VNC-related processes (e.g., `x11vnc`, `vncserver`) coupled with authentication logs and port listening behavior on TCP 5900.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0505 - AN0505"*

Table 6087. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0178#AN0505

Analytic 0550 - AN0550

Abuse of ClickOnce applications where rundll32.exe invokes dfshim.dll with ShOpenVerbApplication or dfsvc.exe spawns unexpected child processes or loads unsigned modules.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0550 - AN0550"*

Table 6088. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0191#AN0550

Analytic 0055 - AN0055

Executable or script payloads lacking symbol information and readable strings that are created or dropped by unusual or short-lived processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0055 - AN0055"*

Table 6089. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0019#AN0055

Analytic 0605 - AN0605

Ransomware encrypts .vmdk, .vmx, .log, or VM config files in VMFS datastores. May rename to .locked or delete/overwrite with encrypted versions. Often correlates with shell commands run through `dcui`, SSH, or vSphere.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0605 - AN0605"*

Table 6090. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0215#AN0605

Analytic 0650 - AN0650

Unsigned processes accessing system memory or launching known credential scraping tools (e.g., osascript, dylib injections) to access the Keychain or sensitive memory regions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0650 - AN0650"*

Table 6091. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0234#AN0650

Analytic 0056 - AN0056

Executable or binary files created without symbol tables or with stripped sections, especially by non-user shell processes or compilers invoked outside standard dev paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0056 - AN0056"*

Table 6092. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0019#AN0056

Analytic 0560 - AN0560

Execution of `ifconfig`, `ip a`, or access to `/proc/net/` indicating collection of local interface and route configuration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0560 - AN0560"*

Table 6093. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0195#AN0560

Analytic 0506 - AN0506

Detection of VNC-based remote control via `screensharingd` activity in Unified Logs along with concurrent remote login activity or suspicious user interaction.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0506 - AN0506"*

Table 6094. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0178#AN0506

Analytic 0065 - AN0065

Adversary stages a lure that references a remote resource (e.g., LNK/SCF/Office template). When the user opens/renders the file or a shell enumerates icons, the host automatically attempts SMB or WebDAV authentication to the attacker host. The chain is: (1) lure file is created or modified in a user-exposed location → (2) user or system accesses the lure → (3) host makes outbound NTLM (SMB 139/445 or WebDAV over 80/443) to an untrusted destination → (4) repeated attempts from multiple users/hosts or from privileged workstations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0065 - AN0065"*

Table 6095. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0022#AN0065

Analytic 0075 - AN0075

Detects unexpected or high-volume HTTP/S/WebSocket communication from suspicious processes (e.g., PowerShell, rundll32) using uncommon user agents or mimicking browser traffic to unusual domains or IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0075 - AN0075"*

Table 6096. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0027#AN0075

Analytic 0705 - AN0705

Monitor for use of native utilities such as wevtutil.exe or PowerShell cmdlets (Get-WinEvent, Get-EventLog) to enumerate or export logs. Unusual access to security or system event channels, especially by non-administrative users or processes, should be correlated with subsequent file export or network transfer activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0705 - AN0705"*

Table 6097. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0255#AN0705

Analytic 0057 - AN0057

Creation of run-only AppleScripts or Mach-O binaries lacking symbol table and string references, especially when dropped by user space scripting engines or staging apps.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0057 - AN0057"*

Table 6098. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0019#AN0057

Analytic 0750 - AN0750

Logon via RDP or WMI by a user account followed by uncommon command execution, file manipulation, or lateral network connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0750 - AN0750"*

Table 6099. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0269#AN0750

Analytic 0507 - AN0507

Detection of adversary enumeration of domain or local group memberships via native tools such as net.exe, PowerShell, or WMI. This activity may precede lateral movement or privilege escalation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0507 - AN0507"*

Table 6100. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0179#AN0507

Analytic 0570 - AN0570

A non-whitelisted process receives TCC camera entitlement (kTCCServiceCamera), opens AppleCamera/AVFoundation device handles, writes .mov/.mp4 artifacts to unusual locations, and/or beacons/exfiltrates soon after.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0570 - AN0570"*

Table 6101. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0197#AN0570

Analytic 0805 - AN0805

Detects creation or modification of crontab entries by non-root users or from abnormal parent processes, followed by the execution of uncommon binaries at scheduled intervals.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0805 - AN0805"*

Table 6102. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0290#AN0805

Analytic 0085 - AN0085

Adversary uses a tool like Ruler to insert a malicious custom form into the user's Outlook mailbox. The form is designed to auto-execute on Outlook startup or on receipt of a specially crafted email.

This results in child processes launched from outlook.exe and possibly network connections or payload loading.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0085 - AN0085"*

Table 6103. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0029#AN0085

Analytic 0508 - AN0508

Detection of group enumeration using commands like 'id', 'groups', or 'getent group', often followed by privilege escalation or SSH lateral movement.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0508 - AN0508"*

Table 6104. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0179#AN0508

Analytic 0580 - AN0580

Detects suspicious registry modifications under `HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors\*\Driver`, DLL loads by `spoolsv.exe` of non-standard or unsigned modules, and abnormal usage of the `AddMonitor` API by non-installation processes. This pattern often indicates an attempt to persist a malicious DLL via the print monitor mechanism, particularly when correlated with creation of files in `C:\Windows\System32` not tied to known patches or installations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0580 - AN0580"*

Table 6105. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0204#AN0580

Analytic 0850 - AN0850

Exploitation of system or application vulnerability (e.g., CVE-based exploit) followed by service crash, restart, or repeated failure within a short time frame, impacting application/system availability.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0850 - AN0850"*

Table 6106. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0304#AN0850

Analytic 0058 - AN0058

Inbound binary payloads transferred over HTTP/S with compressed or encoded headers, lacking signature markers or metadata indicative of compiler/toolchain.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0058 - AN0058"*

Table 6107. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0019#AN0058

Analytic 0059 - AN0059

Detects modification of shell startup/logout scripts such as ~/.bashrc, ~/.bash_profile, or /etc/profile, followed by anomalous process execution or network connections upon interactive or remote shell login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0059 - AN0059"*

Table 6108. Table References

https://attack.mitre.org/detectionstrategies/DET0020#AN0059

Analytic 0095 - AN0095

Identifies adversary behavior that launches commands or invokes APIs to enumerate active processes (e.g., tasklist.exe, Get-Process, or CreateToolhelp32Snapshot). Detects execution combined with parent process lineage, network session context, or remote origin.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0095 - AN0095"*

Table 6109. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0034#AN0095

Analytic 0905 - AN0905

Detects shell-based enumeration of active connections using `netstat`, `lsof -i`, or AppleScript-based system discovery.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0905 - AN0905"*

Table 6110. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0905

Analytic 0950 - AN0950

Detects modification of system or application binaries by monitoring /usr/bin, /bin, and other privileged directories. Correlates file integrity monitoring (FIM) events with unexpected process executions or service restarts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0950 - AN0950"*

Table 6111. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0336#AN0950

Analytic 0590 - AN0590

Detection of suspicious logon behavior using valid domain accounts across multiple hosts, off-hours, or simultaneous sessions from geographically distant locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0590 - AN0590"*

Table 6112. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0210#AN0590

Analytic 0509 - AN0509

Group membership checks via 'dscl', 'dscacheutil', or 'id', typically executed via terminal or automation scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0509 - AN0509"*

Table 6113. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0179#AN0509

Analytic 0606 - AN0606

Encryption of cloud storage objects (e.g., S3 buckets) via Server-Side Encryption (SSE-C) or by replacing objects with encrypted variants. May include API patterns like PutObject with SSE-C headers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0606 - AN0606"*

Table 6114. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0215#AN0606

Analytic 0660 - AN0660

Detection of changes to /etc/rc.local.d/local.sh or rc.local during post-boot script execution with abnormal commands or additions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0660 - AN0660"*

Table 6115. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0237#AN0660

Analytic 0066 - AN0066

Detection of unpacking behavior through abnormal memory allocation, followed by executable code injection and execution from non-image sections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0066 - AN0066"*

Table 6116. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0023#AN0066

Analytic 0067 - AN0067

Correlates ELF file execution with high-entropy writable memory segments and self-modifying code patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0067 - AN0067"*

Table 6117. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0023#AN0067

Analytic 0607 - AN0607

Detection focuses on unauthorized modification of Mach-O binaries to include LC_LOAD_DYLIB headers pointing to malicious dylibs. Behavior is identified via a chain of file metadata changes, removal of code signatures, and subsequent anomalous dylib loads at runtime. Correlation of file changes with lack of authorized updates and process memory mapping of unrecognized or unsigned libraries is crucial.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0607 - AN0607"*

Table 6118. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0216#AN0607

Analytic 0670 - AN0670

Detection of syslog configuration tampering using esxcli system syslog config set or reload. Defender correlates command execution with absence of syslog forwarding activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0670 - AN0670"*

Table 6119. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0239#AN0670

Analytic 0076 - AN0076

Detects curl, wget, Python requests, or custom HTTP clients communicating over non-standard ports, with repetitive or beacon-like patterns or POST-heavy behavior to rare domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0076 - AN0076"*

Table 6120. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0027#AN0076

Analytic 0706 - AN0706

Monitor for suspicious use of commands such as cat, less, grep, or journalctl accessing /var/log/ files. Abnormal enumeration of authentication logs (auth.log, secure) or bulk access to multiple logs in short time windows should be flagged.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0706 - AN0706"*

Table 6121. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0255#AN0706

Analytic 0760 - AN0760

Processes like curl, wget, python, socat, or custom binaries initiating TLS/SSL sessions to non-standard destinations. Defender sees abnormal syscalls for connect(), loading of libssl libraries, and

persistent outbound encrypted traffic from daemons not normally communicating externally.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0760 - AN0760"*

Table 6122. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0273#AN0760

Analytic 0068 - AN0068

Detection of packed Mach-O binaries unpacking into memory and transferring control to dynamically modified code segments.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0068 - AN0068"*

Table 6123. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0023#AN0068

Analytic 0860 - AN0860

Access to local credential/config files (e.g., ~/.aws/credentials) followed by metadata API calls or cloud role assumptions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0860 - AN0860"*

Table 6124. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0307#AN0860

Analytic 0680 - AN0680

Unusual or excessive database/table exports from SaaS database platforms (e.g., Snowflake, Firebase, BigQuery, Airtable) by users or apps not in known analytics or dev groups. Defender observes access patterns outside baseline working hours or with new query templates, and correlates those with audit logs or file downloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0680 - AN0680"*

Table 6125. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0242#AN0680

Analytic 0608 - AN0608

Detects adversary manipulation of Extra Window Memory (EWM) in a GUI process, where the attacker uses SetWindowLong or SetClassLong to redirect function pointers to injected shellcode stored in shared memory, then triggers execution via a window message like SendNotifyMessage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0608 - AN0608"*

Table 6126. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0217#AN0608

Analytic 0086 - AN0086

Outlook form execution upon message receipt or client launch results in automated code execution within user session. Form definitions deviate from standard templates and include script logic or COM object calls embedded in form fields.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0086 - AN0086"*

Table 6127. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0029#AN0086

Analytic 0806 - AN0806

Detects crontab job additions or modifications via `crontab` utility or direct edits, especially those created by interactive users executing hidden or renamed scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0806 - AN0806"*

Table 6128. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0290#AN0806

Analytic 0609 - AN0609

Unusual modifications to service binary paths, registry keys, or DLL load paths resulting in alternate execution flow. Defender observes registry key modifications, suspicious file writes into system directories, and processes loading libraries from abnormal paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0609 - AN0609"*

Table 6129. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0218#AN0609

Analytic 0069 - AN0069

Detects unauthorized access, copying, or modification of Kerberos ccache files (krb5cc_%UID% or krb5.ccache) in /tmp or custom paths defined by KRB5CCNAME. Correlates file access with suspicious processes (e.g., credential dumping tools) and subsequent anomalous Kerberos authentication requests from non-standard processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0069 - AN0069"*

Table 6130. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0024#AN0069

Analytic 0096 - AN0096

Detects execution of common process enumeration utilities (e.g., ps, top, htop) or access to /proc with suspicious ancestry. Correlates command usage with interactive shell context and user role.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0096 - AN0096"*

Table 6131. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0034#AN0096

Analytic 0690 - AN0690

Detects creation of cloud instances, services, or resources in normally unused or unsupported regions, especially following initial account access or credential use from known regions. Correlates resource provisioning across regions with absence of historical usage and alerting from standard logging services (e.g., GuardDuty not enabled in that region).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0690 - AN0690"*

Table 6132. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0247#AN0690

Analytic 0960 - AN0960

Use of instance metadata tokens across instances or misuse of short-lived tokens issued for different roles.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0960 - AN0960"*

Table 6133. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0338#AN0960

Analytic 0906 - AN0906

Detects shell or API usage of `esxcli network ip connection list` or `netstat` to enumerate ESXi host connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0906 - AN0906"*

Table 6134. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0906

Analytic 0770 - AN0770

Detection of rogue Domain Controller registration and Active Directory replication abuse by correlating: (1) creation/modification of nTDSDSA and server objects in the Configuration partition, (2) unexpected usage of Directory Replication Service SPNs (GC/ or E3514235-4B06-11D1-AB04-00C04FC2DCD2), (3) replication RPC calls (DrsAddEntry, DrsReplicaAdd, GetNCChanges) originating from non-DC hosts, and (4) Kerberos authentication by non-DC machines using DRS-related SPNs. These events in combination, especially from hosts outside the Domain Controllers OU, may indicate DCShadow or rogue DC activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0770 - AN0770"*

Table 6135. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0276#AN0770

Analytic 0077 - AN0077

Detects applications such as Automator, AppleScript, or LaunchDaemons invoking HTTP/S traffic to non-standard domains or using suspicious headers (e.g., Base64 in URIs or cookie fields).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0077 - AN0077"*

Table 6136. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0027#AN0077

Analytic 0707 - AN0707

Detect abnormal access to unified logs via log show or fs_usage targeting system log files. Monitor for execution of shell utilities (cat, grep) against /var/log/system.log and for plist modifications enabling verbose logging.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0707 - AN0707"*

Table 6137. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0255#AN0707

Analytic 0078 - AN0078

Detects HTTP or HTTPS communication initiated by shell-based scripts or management daemons, especially those reaching public IPs over ports 80/443 using embedded curl or wget.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0078 - AN0078"*

Table 6138. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0027#AN0078

Analytic 0807 - AN0807

Detects direct modification of crontab entries in /var/spool/cron/crontabs/root or /etc/rc.local.d/local.sh followed by execution of scripts linked to lateral movement or malware persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0807 - AN0807"*

Table 6139. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0290#AN0807

Analytic 0708 - AN0708

Monitor for cloud API calls that export or collect guest or system logs. Abnormal use of Azure VM Agent's CollectGuestLogs.exe or AWS CloudWatch GetLogEvents across multiple instances should be correlated with lateral movement or data staging.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0708 - AN0708"*

Table 6140. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0255#AN0708

Analytic 0780 - AN0780

Monitor launchd service definitions and property list (.plist) modifications for non-standard executables. Detect unauthorized processes registered as launch daemons or agents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0780 - AN0780"*

Table 6141. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0279#AN0780

Analytic 0087 - AN0087

Detects modifications to IAM conditions or policies that alter authentication behavior, such as adding permissive trusted IPs, removing MFA requirements, or changing regional access restrictions. Behavioral detection focuses on anomalous policy updates tied to privileged accounts and subsequent suspicious logon activity from previously blocked regions or devices.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0087 - AN0087"*

Table 6142. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0030#AN0087

Analytic 0870 - AN0870

Detection of fake or spoofed macOS Security & Privacy GUIs showing healthy status after XProtect, Gatekeeper, or AV processes are disabled. Correlates user-space UI process creation with terminated or missing security daemons.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0870 - AN0870"*

Table 6143. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0311#AN0870

Analytic 0079 - AN0079

Detects Web protocol misuse such as encoded HTTP headers, WebSocket upgrade requests with abnormal payloads, or TLS handshake anomalies suggesting embedded C2 channels.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0079 - AN0079"*

Table 6144. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0027#AN0079

Analytic 0790 - AN0790

ESXi services (vmx, hostd) generating outbound HTTPS POST requests to text storage sites. Defender perspective: anomalous datastore or log reads chained with traffic to pastebin-like destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0790 - AN0790"*

Table 6145. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0284#AN0790

Analytic 0097 - AN0097

Monitors execution of ps, top, or launchctl with unusual parent processes or from terminal scripts. Also detects AppleScript-based process listing or `system_profiler SPApplicationsDataType` misuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0097 - AN0097"*

Table 6146. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0034#AN0097

Analytic 0970 - AN0970

Kernel or userland processes generating high-rate network traffic (ICMP, UDP, TCP SYN) beyond expected interface throughput or user behavior norms.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0970 - AN0970"*

Table 6147. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0343#AN0970

Analytic 0907 - AN0907

Detects interactive or automated use of CLI commands like `show ip sockets`, `show tcp brief`, or SNMP queries for active sessions on routers/switches.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0907 - AN0907"*

Table 6148. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0907

Analytic 0709 - AN0709

Monitor ESXi shell or API access to host logs under /var/log/. Abnormal enumeration of vmkernel.log, hostd.log, or vpxa.log by unauthorized accounts should be flagged.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0709 - AN0709"*

Table 6149. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0255#AN0709

Analytic 0880 - AN0880

Adversaries create the 'Office Test\Special\Perf' registry key and specify a malicious DLL path that is auto-loaded when an Office application starts. This DLL is injected into the Office process memory space and can provide persistent execution without requiring macro enablement.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0880 - AN0880"*

Table 6150. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0315#AN0880

Analytic 0088 - AN0088

Detects suspicious updates to conditional access or MFA enforcement policies in identity providers such as Entra ID, Okta, or JumpCloud. Focus is on removal of policy blocks, addition of broad exclusions, or registration of adversary-controlled MFA methods, followed by anomalous login activity that takes advantage of the modified policies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0088 - AN0088"*

Table 6151. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0030#AN0088

Analytic 0808 - AN0808

Detects web console login events followed by read-only or metadata retrieval activity from GUI sources (e.g., browser session, mobile client) rather than API/CLI sources. Correlates across

CloudTrail, IAM identity logs, and user-agent context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0808 - AN0808"*

Table 6152. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0291#AN0808

Analytic 0809 - AN0809

Detects successful login to cloud identity portals (e.g., Okta, Azure AD, Google Identity) from atypical geolocations, devices, or user agents immediately followed by dashboard/portal navigation to sensitive pages such as user or app configuration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0809 - AN0809"*

Table 6153. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0291#AN0809

Analytic 0980 - AN0980

Unusual use of screen capture APIs (e.g., CopyFromScreen) or command-line tools to write image files to disk.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0980 - AN0980"*

Table 6154. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0346#AN0980

Analytic 0098 - AN0098

Detects process enumeration using `esxcli system process list` or `ps` on ESXi shell or via unauthorized SSH sessions. Correlates with interactive sessions and abnormal user roles.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0098 - AN0098"*

Table 6155. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0034#AN0098

Analytic 0908 - AN0908

Detects enumeration of cloud network interfaces, VPCs, subnets, or peer connections using CLI or SDKs (e.g., AWS CLI, Azure CLI, GCloud CLI).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0908 - AN0908"*

Table 6156. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0320#AN0908

Analytic 0089 - AN0089

Execution of binaries with invalid digital signatures, where metadata claims code is signed but validation fails. Behavior is often correlated with suspicious parent processes or unexpected execution paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0089 - AN0089"*

Table 6157. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0031#AN0089

Analytic 0890 - AN0890

Unusual ESXi shell commands disabling syslog forwarding or stopping hostd/vpxa daemons. Detect modifications to firewall rules on ESXi host or disabling of lockdown mode.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0890 - AN0890"*

Table 6158. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0890

Analytic 0990 - AN0990

Detects unauthorized applications or scripts accessing sensitive data followed by establishing encrypted outbound communication to rare external destinations or with abnormal byte ratios.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0990 - AN0990"*

Table 6159. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0348#AN0990

Analytic 0099 - AN0099

Monitors CLI-based execution of `show process` or equivalent on routers/switches. Correlates unusual device access, unauthorized roles, or config mode changes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0099 - AN0099"*

Table 6160. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0034#AN0099

Analytic 0909 - AN0909

Unusual execution of virtualization binaries (VBoxManage.exe, vmware-vmx.exe, vmwp.exe) with headless or suppressed notification arguments. Registry and service modifications linked to virtualization installs. Defender view: anomalies in process creation, service metadata, and registry writes tied to enabling hidden VMs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0909 - AN0909"*

Table 6161. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0321#AN0909

Analytic 0111 - AN0111

Inspect unified logs for anomalous DNS resolutions triggered by non-network applications. Flag repeated connections to newly registered or algorithmically generated domains. Correlate with endpoint process telemetry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0111 - AN0111"*

Table 6162. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0039#AN0111

Analytic 1101 - AN1101

Adversary invokes 'dpkg -l', 'rpm -qa', or other package managers via shell or script to enumerate installed software.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1101 - AN1101"*

Table 6163. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0392#AN1101

Analytic 1011 - AN1011

Monitor unified logs and Mail.app activity for repetitive incoming messages with attachments. Defenders should look for large volumes of incoming mail stored under ~/Library/Mail with unusual timing or repetitive subjects.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1011 - AN1011"*

Table 6164. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0355#AN1011

Analytic 1110 - AN1110

Web servers (e.g., httpd) spawning abnormal processes post file upload into /Library/WebServer/Documents or /usr/local/var/www

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1110 - AN1110"*

Table 6165. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0394#AN1110

Analytic 0121 - AN0121

Detection of system calls or commands accessing system locale (e.g., 'defaults read -g AppleLocale', 'systemsetup -gettimezone'). Correlate with unusual parent processes or execution contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0121 - AN0121"*

Table 6166. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0043#AN0121

Analytic 0211 - AN0211

Detects abuse of Mono/.NET Core environments to execute VB-like scripts, often in environments with Office emulation or WINE. Focus is on rare invocations of scripting hosts like mono.exe or .NET shells, often seen in spam filtering or forensic labs with Office support.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0211 - AN0211"*

Table 6167. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0076#AN0211

Analytic 1021 - AN1021

Tools such as `tor`, `nglite`, `proxychains`, `chisel`, or custom daemons repeatedly initiate outbound sessions to multiple nodes before final destination. This behavior is abnormal for Linux services outside of VPN, monitoring, or CDN relay contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1021 - AN1021"*

Table 6168. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0359#AN1021

Analytic 1201 - AN1201

Detects attempts to access or enumerate cloud password/secrets storage services such as AWS Secrets Manager, Azure Key Vault, or GCP Secret Manager. Monitors API calls for abnormal enumeration or bulk retrieval of secrets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1201 - AN1201"*

Table 6169. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0430#AN1201

Analytic 0112 - AN0112

Monitor esxcli and syslog records for DNS resolver changes or repeated queries to unusual external domains by management agents. Detect unauthorized changes to VM or host network settings that redirect DNS lookups.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0112 - AN0112"*

Table 6170. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0039#AN0112

Analytic 1210 - AN1210

Detection centers on DYLD_INSERT_LIBRARIES and DYLD_LIBRARY_PATH abuse. Defender perspective: monitor for modification of these environment variables in shell or plist files, file creation of dylibs in user-controlled paths, and correlation of environment variable usage with

unexpected module loads by user applications. Suspicious indicators include processes with DYLD_INSERT_LIBRARIES set, execution of applications loading untrusted dylibs, and anomalies in module load history.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1210 - AN1210"*

Table 6171. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0435#AN1210

Analytic 1120 - AN1120

LaunchAgent or launchd recurring jobs initiating data transfer to consistent external IPs or domains with repeat timing signatures.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1120 - AN1120"*

Table 6172. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0399#AN1120

Analytic 1102 - AN1102

Adversary runs 'system_profiler SPApplicationsDataType' or queries plist files to enumerate software via Terminal or scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1102 - AN1102"*

Table 6173. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0392#AN1102

Analytic 2011 - AN2011

Much of this activity will take place outside the visibility of the target organization, making detection of this behavior difficult. Detection efforts may be focused on related stages of the adversary lifecycle, such as during exfiltration (ex: [Transfer Data to Cloud Account](https://attack.mitre.org/techniques/T1537)).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2011 - AN2011"*

Table 6174. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0879#AN2011

Analytic 1012 - AN1012

Burst of incomplete TCP handshakes (e.g., SYN floods) or uncorrelated ACK packets targeting the state table resulting in OS resource exhaustion.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1012 - AN1012"*

Table 6175. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0356#AN1012

Analytic 1031 - AN1031

Detects adversarial abuse of WMI to execute local or remote commands via WMIC, PowerShell, or COM API through a multi-event chain: process creation, command execution, and corresponding network connection if remote.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1031 - AN1031"*

Table 6176. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0364#AN1031

Analytic 1103 - AN1103

Adversary uses cloud-native APIs or CLI (e.g., AWS Systems Manager, Azure Resource Graph) to list installed software on cloud workloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1103 - AN1103"*

Table 6177. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0392#AN1103

Analytic 1301 - AN1301

Detects upload of malicious or unusual file types into cloud-shared folders, followed by user downloads or interactions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1301 - AN1301"*

Table 6178. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0471#AN1301

Analytic 0113 - AN0113

Detects adversary activity that removes persistence artifacts such as services, registry keys, scheduled tasks, user accounts, and binaries through commands like `sc delete`, `schtasks /delete`, or `reg delete`.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0113 - AN0113"*

Table 6179. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0040#AN0113

Analytic 0311 - AN0311

Monitoring modification and execution of user or system logon scripts such as in registry Run keys or startup folders.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0311 - AN0311"*

Table 6180. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0112#AN0311

Analytic 1130 - AN1130

Discovery of connected SaaS applications, APIs, or configurations within platforms like Salesforce, Slack, or Zoom. Defender perspective includes enumeration of available integrations, abnormal querying of service metadata, and follow-on attempts to exploit or persist via discovered services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1130 - AN1130"*

Table 6181. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0402#AN1130

Analytic 1310 - AN1310

Detects file access to mbox/maildir files in conjunction with curl/wget/postfix execution, or anomalous shell scripts harvesting user mail directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1310 - AN1310"*

Table 6182. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0476#AN1310

Analytic 0131 - AN0131

Detects adversaries accessing remote mail systems (e.g., Exchange Online, O365) using stolen credentials or OAuth tokens, followed by scripted access to mailbox contents via PowerShell, AADInternals, or unattended API queries. Detection focuses on abnormal logon sessions, user agents, IP locations, and scripted or tool-based email data access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0131 - AN0131"*

Table 6183. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0048#AN0131

Analytic 1013 - AN1013

Flood of spoofed SYN or ACK packets causing exhaustion of OS TCP state table, potentially via user-space utilities or kernel-level DoS agents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1013 - AN1013"*

Table 6184. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0356#AN1013

Analytic 1104 - AN1104

Adversary uses 'esxcli software vib list' to enumerate installed VIBs, drivers, and modules.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1104 - AN1104"*

Table 6185. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0392#AN1104

Analytic 0141 - AN0141

Suspicious file creation or modification in directories ignored by XProtect or AV exclusions (e.g., ~/Library, temporary cache directories). Defender perspective: monitor file events in ignored paths with correlation to execution or persistence activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0141 - AN0141"*

Table 6186. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0051#AN0141

Analytic 1410 - AN1410

Adversary mounts a USB device and begins enumerating, copying, or compressing files using scripting engines, cmd, or remote access tools.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1410 - AN1410"*

Table 6187. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0511#AN1410

Analytic 1014 - AN1014

Adversary tool/script issuing mass SYN/ACK floods that degrade OS responsiveness and interrupt service response on macOS endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1014 - AN1014"*

Table 6188. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0356#AN1014

Analytic 1401 - AN1401

Detects memory-based injection by monitoring `task_for_pid`, `mach_vm_write`, and dylib injection patterns through `DYLD_INSERT_LIBRARIES` or manual memory mapping.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1401 - AN1401"*

Table 6189. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0508#AN1401

Analytic 0411 - AN0411

Adversary spawns command-line tools (e.g., del, cipher /w, SDelete) or scripts to recursively delete or overwrite user/system files. This may be correlated with abnormal file IO activity, registry writes, or tampering in critical system directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0411 - AN0411"*

Table 6190. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0146#AN0411

Analytic 0114 - AN0114

Detects removal of persistence artifacts such as crontab entries, systemd service units, and malicious user accounts through commands like `crontab -r`, `rm /etc/systemd/system/*.service`, or `userdel`.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0114 - AN0114"*

Table 6191. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0040#AN0114

Analytic 1041 - AN1041

Use of file enumeration commands (e.g., 'ls', 'find', 'locate') executed by suspicious users or scripts accessing broad file hierarchies or restricted directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1041 - AN1041"*

Table 6192. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0370#AN1041

Analytic 1140 - AN1140

Outbound spoofed traffic to known amplification protocols (e.g., DNS, NTP, Memcached) combined with abnormal network traffic volume targeting remote reflectors, resulting in disproportionate traffic returned to a victim

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1140 - AN1140"*

Table 6193. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0408#AN1140

Analytic 1051 - AN1051

Detection of anomalous or unauthorized mailbox delegation activity (e.g., Add-MailboxPermission, Default/Anonymous mailbox permissions, Gmail delegation setup).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1051 - AN1051"*

Table 6194. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0373#AN1051

Analytic 1501 - AN1501

Detects adversary abuse of Transactional NTFS (TxF) and undocumented process loading mechanisms (e.g., NtCreateProcessEx) to create a hollowed process from an uncommitted, maliciously tainted file image in memory, later executed via NtCreateThreadEx.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1501 - AN1501"*

Table 6195. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0544#AN1501

Analytic 1510 - AN1510

Use of ESXi web interface plugins or vSphere extensions to embed persistent malicious scripts or services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1510 - AN1510"*

Table 6196. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0547#AN1510

Analytic 0151 - AN0151

Outlook or Word used to forward suspicious internal attachments with macro content. Defender observes attachment forwarding, auto-opening behaviors, or macro prompt interactions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0151 - AN0151"*

Table 6197. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0054#AN0151

Analytic 0115 - AN0115

Detects deletion of launch agents (~/Library/LaunchAgents/) and launch daemons (/Library/LaunchDaemons/), especially after suspicious process execution or when tied to known persistence methods.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0115 - AN0115"*

Table 6198. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0040#AN0115

Analytic 1150 - AN1150

Monitor unified logs for manipulation of proxy configurations, DNS resolution, or filtering rules. Adversaries may redirect responses or use trusted domains that later resolve to malicious C2 infrastructure.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1150 - AN1150"*

Table 6199. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0411#AN1150

Analytic 1015 - AN1015

Execution of utilities (e.g., ping, tracert, Test-NetConnection) or scripted methods to test Internet connectivity by interacting with external IPs/domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1015 - AN1015"*

Table 6200. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0357#AN1015

Analytic 1105 - AN1105

Multiple AWS CloudTrail events indicating temporary privilege escalation via PassRole and AssumeRole targeting newly created services or non-interactive infrastructure.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1105 - AN1105"*

Table 6201. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0393#AN1105

Analytic 0511 - AN0511

Creation or modification of stored procedures invoking xp_cmdshell or CLR assemblies for command execution and persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0511 - AN0511"*

Table 6202. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0181#AN0511

Analytic 1061 - AN1061

Unauthorized or anomalous loading of kernel-mode drivers or DLLs, concealed services, or abnormal modification of boot components indicative of rootkit activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1061 - AN1061"*

Table 6203. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0377#AN1061

Analytic 1106 - AN1106

Token creation or access delegation where a user impersonates a higher-privileged service account or performs domain-wide delegation actions, such as GCP's serviceAccountTokenCreator or Workspace impersonation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1106 - AN1106"*

Table 6204. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0393#AN1106

Analytic 1610 - AN1610

Abuse of JamPlus.exe to launch malicious payloads via crafted .jam files, resulting in abnormal process creation, command execution, or artifact generation outside of standard development workflows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1610 - AN1610"*

Table 6205. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0585#AN1610

Analytic 1160 - AN1160

Programmatic or excessive access to file shares, SharePoint, or database repositories by users not

typically interacting with them. This includes abnormal access by privileged accounts, enumeration of large numbers of files, or downloads of sensitive content in bursts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1160 - AN1160"*

Table 6206. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0413#AN1160

Analytic 0161 - AN0161

Detection of a process or script that accesses a common web service to retrieve content containing obfuscated indicators of a secondary C2 server (dead drop resolver behavior).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0161 - AN0161"*

Table 6207. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0058#AN0161

Analytic 1016 - AN1016

Execution of ping, traceroute, or curl/wget against public IPs/domains to verify Internet reachability.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1016 - AN1016"*

Table 6208. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0357#AN1016

Analytic 0116 - AN0116

Detects adversary removal of persistence implants (e.g., rc.local entries or crontab injections) via CLI (`rm`, `sed`, `crontab -r`) and deletion of startup or management scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0116 - AN0116"*

Table 6209. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0040#AN0116

Analytic 1601 - AN1601

Process using URLSession or similar API to fetch from web services without any response handling, indicative of one-way C2 channels.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1601 - AN1601"*

Table 6210. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0581#AN1601

Analytic 0611 - AN0611

Abuse of DYLD_INSERT_LIBRARIES or hijacking framework paths for malicious libraries. Defender observes processes invoking abnormal dylibs, modified plist files, or persistence entries pointing to altered binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0611 - AN0611"*

Table 6211. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0218#AN0611

Analytic 1017 - AN1017

Execution of ping, traceroute, or network utility tools to external destinations; may include `scutil` or system_profiler.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1017 - AN1017"*

Table 6212. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0357#AN1017

Analytic 1170 - AN1170

Detects usage of FTP, SCP, or TFTP by non-interactive shells or automation scripts transferring large data volumes to untrusted IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1170 - AN1170"*

Table 6213. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0416#AN1170

Analytic 1107 - AN1107

Detection of ApplicationImpersonation role assignment or delegated mailbox access to service principals or rarely used users, especially outside of normal hours or geographic norms.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1107 - AN1107"*

Table 6214. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0393#AN1107

Analytic 0171 - AN0171

Disabling or modifying the Linux Audit system through process termination (auditd killed), service management (systemctl stop auditd), or tampering with rule/configuration files (/etc/audit/audit.rules, audit.conf). Defender view: suspicious execution of auditctl/systemctl commands, file modifications to audit rules, or sudden absence of audit logs correlated with privileged execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0171 - AN0171"*

Table 6215. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0062#AN0171

Analytic 1071 - AN1071

Adversaries using bash scripts or tools to recursively enumerate user home directories, config files, or SSH keys.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1071 - AN1071"*

Table 6216. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0380#AN1071

Analytic 0711 - AN0711

Unusual access to SSH agent sockets in /tmp/ or /private/tmp, process access to another user's $SSH_AUTH_SOCK, and lateral SSH activity without corresponding login events. Defender view: correlation of socket access with anomalous network flows to internal systems.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0711 - AN0711"*

Table 6217. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0256#AN0711

Analytic 0117 - AN0117

Adversary with write access to storage modifies lifecycle policies (e.g., via PutBucketLifecycle) to schedule rapid object deletion across one or more storage buckets. This is often used to trigger impact (destruction), remove logs (defense evasion), or force extortion (ransomware).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0117 - AN0117"*

Table 6218. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0041#AN0117

Analytic 1701 - AN1701

The user is prompted for approval when an application requests device administrator permissions. Application vetting services can check for the string `BIND_DEVICE_ADMIN` in the application's manifest. This indicates it can prompt the user for device administrator permissions. The user can see which applications are registered as device administrators in the device settings.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1701 - AN1701"*

Table 6219. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0630#AN1701

Analytic 1710 - AN1710

System Network Connections Discovery can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1710 - AN1710"*

Table 6220. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0636#AN1710

Analytic 1180 - AN1180

Monitor unified DNS logs for abnormal domain queries with low lexical similarity to known domains, repeated failed lookups, and random string structures. Cross-check with process logs to confirm unusual origins (non-browser apps).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1180 - AN1180"*

Table 6221. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0419#AN1180

Analytic 1108 - AN1108

Unexpected file creation in web directories followed by web server processes (e.g., w3wp.exe) spawning command shells or script interpreters (e.g., cmd.exe, powershell.exe)

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1108 - AN1108"*

Table 6222. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0394#AN1108

Analytic 0181 - AN0181

Execution of processes using nohup or shell redirection to ignore SIGHUP and continue running after session termination. Defender perspective: correlation between commands including nohup, disowned jobs, or & suffix with continued process execution after parent terminal exit.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0181 - AN0181"*

Table 6223. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0067#AN0181

Analytic 1081 - AN1081

Detects bash, sh, zsh, or BusyBox shell execution initiated via remote sessions, unauthorized users, or embedded within secondary script interpreters. Focus is on chained behavior: shell > suspicious commands > network discovery or persistence indicators.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1081 - AN1081"*

Table 6224. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0384#AN1081

Analytic 0811 - AN0811

Detects SaaS web login followed by dashboard or web GUI page views from unfamiliar locations,

devices, or access patterns. Identifies use of sensitive reporting or configuration consoles accessed from high-risk accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0811 - AN0811"*

Table 6225. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0291#AN0811

Analytic 0118 - AN0118

Detects abuse of verclsid.exe to execute COM objects by monitoring process creation, CLSID arguments, DLLs or scriptlet engines loaded into memory, and If the CLSID points to remote SCT/HTA content, verclsid.exe makes outbound connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0118 - AN0118"*

Table 6226. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0042#AN0118

Analytic 1018 - AN1018

Execution of `ping`, `vmkping`, or `curl` from shell or through automation jobs/scripts to verify Internet egress.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1018 - AN1018"*

Table 6227. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0357#AN1018

Analytic 1801 - AN1801

Application vetting services could look for use of the accessibility service or features that typically require root access. The user can see a list of applications that can use accessibility services in the device settings.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1801 - AN1801"*

Table 6228. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0690#AN1801

Analytic 1810 - AN1810

Network service scanning can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1810 - AN1810"*

Table 6229. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0696#AN1810

Analytic 0191 - AN0191

Phishing via Office documents containing embedded macros or links that spawn processes. Detection relies on correlating Office application logs with suspicious child process execution and outbound network connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0191 - AN0191"*

Table 6230. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0070#AN0191

Analytic 0911 - AN0911

Execution of virtualization binaries (Parallels, VMware Fusion, VirtualBox) with arguments to hide UI. File monitoring for plist modifications indicating hidden virtualization behavior. Defender perspective: tracking process lineage and file modifications in system configs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0911 - AN0911"*

Table 6231. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0321#AN0911

Analytic 1019 - AN1019

Detection of excessive or programmatic access to Confluence spaces or pages, particularly by privileged users, through a combination of access logs, API usage, and identity context. Correlates logon sessions, user roles, and abnormal document viewing or export behavior. Identifies burst access patterns and tools/scripts abusing the Confluence API for mass enumeration or data scraping.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1019 - AN1019"*

Table 6232. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0358#AN1019

Analytic 1190 - AN1190

Detects command-line tools, agents, or scripts making outbound HTTPS connections to popular web services like Discord, Slack, Dropbox, or Graph API in an unusual context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1190 - AN1190"*

Table 6233. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0425#AN1190

Analytic 1109 - AN1109

File creation of unauthorized script (e.g., .php, .sh) in /var/www/html followed by execution of unexpected system utilities (e.g., curl, bash, nc) by apache/nginx

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1109 - AN1109"*

Table 6234. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0394#AN1109

Analytic 0119 - AN0119

Unusual process or API usage attempting to query system locale, timezone, or keyboard layout (e.g., calls to GetLocaleInfoW, GetTimeZoneInformation). Detection can be enhanced by correlating with processes not typically associated with system configuration queries, such as unknown binaries or scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0119 - AN0119"*

Table 6235. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0043#AN0119

Analytic 1091 - AN1091

Detects anomalous ARP traffic or cache modifications on Windows endpoints that indicate ARP poisoning. Behavioral focus is on multiple IP addresses resolving to a single MAC, or unsolicited ARP replies from unauthorized devices.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1091 - AN1091"*

Table 6236. Table References

Links

Analytic 2012 - AN2012

Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders.

Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2012 - AN2012"*

Table 6237. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0880#AN2012

Analytic 0122 - AN0122

Detection of queries to instance metadata services (e.g., AWS IMDS, Azure Metadata Service) for availability zone, region, or network geolocation details. Correlation with non-management accounts or non-standard workloads may indicate adversary reconnaissance.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0122 - AN0122"*

Table 6238. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0043#AN0122

Analytic 1220 - AN1220

Execution of SyncAppvPublishingServer.vbs through wscript.exe with a command-line containing embedded PowerShell, proxying malicious PowerShell execution through a Microsoft-signed VBScript interpreter to evade detection and restrictions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1220 - AN1220"*

Table 6239. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0440#AN1220

Analytic 1022 - AN1022

LaunchAgents or LaunchDaemons initiate persistent Tor or relay processes that make encrypted outbound connections. May be paired with sandbox bypasses or unsigned executables communicating over SOCKS proxies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1022 - AN1022"*

Table 6240. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0359#AN1022

Analytic 1202 - AN1202

Monitor email message traces and headers for failed SPF, DKIM, or DMARC checks indicating spoofed sender identities. Correlate abnormal sender domains or mismatched return-paths with elevated spoofing likelihood.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1202 - AN1202"*

Table 6241. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0431#AN1202

Analytic 0212 - AN0212

Execution of file transfer or network access activity through non-primary interfaces (e.g., WiFi, Bluetooth, cellular) by processes not typically associated with such behavior (e.g., rundll32, powershell, regsvr32).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0212 - AN0212"*

Table 6242. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0077#AN0212

Analytic 0221 - AN0221

Adversary targets macOS-hosted public services (e.g., nginx, node). Chain: suspicious inbound request → service crash/5xx → service spawns shell or writes file → new outbound connection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0221 - AN0221"*

Table 6243. Table References

https://attack.mitre.org/detectionstrategies/DET0080#AN0221

Analytic 2021 - AN2021

Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders.

Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2021 - AN2021"*

Table 6244. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0889#AN2021

Analytic 1023 - AN1023

Outbound encrypted traffic initiated from hypervisor shell or via VM backdoor mechanisms to relays in VPS infrastructure, especially if traversing multiple nodes before reaching Internet destination. Packet captures or firewall logs show non-VM communication paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1023 - AN1023"*

Table 6245. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0359#AN1023

Analytic 0312 - AN0312

Detection of changes or execution of shell initialization scripts like .bashrc, .profile, or /etc/profile for persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0312 - AN0312"*

Table 6246. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0112#AN0312

Analytic 1203 - AN1203

Detects spoofed emails by analyzing mail server logs (e.g., Postfix, Sendmail) for mismatched header fields, failed SPF/DKIM checks, and anomalies in SMTP proxy logs. Defender observes discrepancies between sending domain, return-path domain, and message metadata.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1203 - AN1203"*

Table 6247. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0431#AN1203

Analytic 0132 - AN0132

Monitors programmatic access to user mailboxes in cloud-based email systems (e.g., O365, Exchange Online) using APIs or tokens. Focuses on OAuth misuse, suspicious MailItemsAccessed patterns, scripted keyword searches, and connections from untrusted agents or locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0132 - AN0132"*

Table 6248. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0048#AN0132

Analytic 1320 - AN1320

Detects unauthorized modifications to login-facing web server files (e.g., index.php, login.js) typically tied to VPN, SSO, or intranet portals. Correlates suspicious file changes with remote access artifacts or web shell behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1320 - AN1320"*

Table 6249. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0480#AN1320

Analytic 0213 - AN0213

Use of `rfkill`, `nmcli`, or low-level tools (e.g., `iw`, `hcitool`, `pppd`) to enable alternate interfaces followed by data transfer via non-primary NICs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0213 - AN0213"*

Table 6250. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0077#AN0213

Analytic 0231 - AN0231

Modification of user desktop backgrounds, login screen messages, or system banners by

adversaries using admin privileges or script execution. May coincide with tampering in /Library/Desktop Pictures/ or use of AppleScript.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0231 - AN0231"*

Table 6251. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0082#AN0231

Analytic 2013 - AN2013

If infrastructure or patterns in the malicious web content related to SEO poisoning or [Drive-by Target](https://attack.mitre.org/techniques/T1608/004) have been previously identified, internet scanning may uncover when an adversary has staged web content supporting a strategic web compromise. Much of this activity will take place outside the visibility of the target organization, making detection of this behavior difficult. Detection efforts may be focused on other phases of the adversary lifecycle, such as [Drive-by Compromise](https://attack.mitre.org/techniques/T1189) or [Exploitation for Client Execution](https://attack.mitre.org/techniques/T1203).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2013 - AN2013"*

Table 6252. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0881#AN2013

Analytic 2031 - AN2031

Detection of HTTP outbound requests with inconsistent or spoofed User-Agent headers from command-line tools (e.g., curl, wget, python requests) following interactive user shells or scheduled jobs outside of normal user session behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 2031 - AN2031"*

Table 6253. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0898#AN2031

Analytic 1230 - AN1230

User-space tools (e.g., `socat`, `ncat`, `iptables`, `ssh`) used in non-standard ways to establish reverse shells, port-forwarding, or inter-host connections. Often chained with uncommon outbound destinations or SSH tunnels.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1230 - AN1230"*

Table 6254. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0445#AN1230

Analytic 1302 - AN1302

Detects embedded macros or scripts added to shared documents or use of external references to execute code.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1302 - AN1302"*

Table 6255. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0471#AN1302

Analytic 0123 - AN0123

Installation of a new browser extension followed by suspicious file writes or outbound network connections to untrusted domains by the browser process.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0123 - AN0123"*

Table 6256. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0044#AN0123

Analytic 1032 - AN1032

Correlation of Registry key creation/modification events under known Run/Startup keys with new or unusual binary paths or script-based payloads. Multi-event detection includes registry modification followed by process execution from non-standard directories or abnormal parent-child process relationships.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1032 - AN1032"*

Table 6257. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0365#AN1032

Analytic 0321 - AN0321

Use of non-enterprise email or messaging services in Thunderbird, Evolution, or browsers leading to suspicious file downloads and subsequent execution. Defender view includes browser-initiated downloads of unexpected content and shell or interpreter processes launched post-download.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0321 - AN0321"*

Table 6258. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0115#AN0321

Analytic 0142 - AN0142

Correlate command executions involving 'sudo' with elevated effective user ID (euid=0), especially when tty_tickets is disabled or timestamp_timeout is actively abused.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0142 - AN0142"*

Table 6259. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0052#AN0142

Analytic 1204 - AN1204

Detects suspicious inbound mail traffic where SPF/DKIM/DMARC authentication fails or where sender and return-path domains mismatch, observable in Apple Mail unified logs or MDM-controlled logging pipelines.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1204 - AN1204"*

Table 6260. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0431#AN1204

Analytic 1420 - AN1420

Detects escalation via vulnerable setuid binaries or kernel modules, often chained with unusual access to /proc/kallsyms or /dev/kmem.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1420 - AN1420"*

Table 6261. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0514#AN1420

Analytic 0124 - AN0124

Installation of malicious .mobileconfig profiles or browser extension plist entries followed by abnormal browser child process activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0124 - AN0124"*

Table 6262. Table References

Links

Table 6280. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0883#AN2015

Analytic 1502 - AN1502

Monitor for suspicious use of cloud-native administrative command services (e.g., AWS Systems Manager Run Command, Azure RunCommand, GCP OS Config) to execute code inside VMs. Detect anomalies such as commands/scripts executed by unexpected users, execution outside of maintenance windows, or commands initiated by service accounts not normally tied to administration. Correlate cloud control-plane activity logs with host-level execution (process creation, script execution) to validate if commands materialized inside the guest OS.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1502 - AN1502"*

Table 6281. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0545#AN1502

Analytic 1250 - AN1250

Detects unauthorized modifications to PAM configuration files or shared object modules. Correlates file modification events under /etc/pam.d/ or /lib/security/ with unusual authentication activity such as multiple simultaneous logins, off-hours logins, or logons without corresponding physical/VPN access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1250 - AN1250"*

Table 6282. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0454#AN1250

Analytic 1205 - AN1205

Correlates Office 365 or Google Workspace audit logs for spoofed sender addresses, failed email authentication, and anomalies in message delivery metadata. Defender observes failed SPF/DKIM checks and domain mismatches tied to suspicious campaigns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1205 - AN1205"*

Table 6283. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0431#AN1205

Analytic 0215 - AN0215

Detects adversarial use of cloud APIs for command execution, resource control, or reconnaissance. Focuses on CLI/SDK/scripting language abuse via stolen credentials or in-browser Cloud Shells. Monitors for anomalous API calls chained with authentication context shifts (e.g., stolen token →

privileged action) and cross-service impacts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0215 - AN0215"*

Table 6284. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0078#AN0215

Analytic 1026 - AN1026

Behavioral detection of domain group enumeration via ldapsearch or custom scripts leveraging LDAP over the network.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1026 - AN1026"*

Table 6285. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0360#AN1026

Analytic 0216 - AN0216

Detection of anomalous RDP or remote service session activity where a logon session is hijacked rather than newly created. Indicators include mismatched user credentials vs. active session tokens, service session takeovers without corresponding successful logon events, or RDP shadowing activity without user consent.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0216 - AN0216"*

Table 6286. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0079#AN0216

Analytic 1602 - AN1602

ESXi shell or scheduled tasks initiating outbound HTTPS to known public services without inbound return or loggable response, used to fetch instructions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1602 - AN1602"*

Table 6287. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0581#AN1602

Analytic 1062 - AN1062

Abnormal loading of kernel modules, direct tampering with /dev, /proc, or LD_PRELOAD behaviors hiding processes or files.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1062 - AN1062"*

Table 6288. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0377#AN1062

Analytic 0162 - AN0162

Correlate unauthorized or anomalous file modifications, deletions, or metadata changes with suspicious process execution or API calls. Detect abnormal changes to structured data (e.g., database files, logs, financial records) outside expected business process activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0162 - AN0162"*

Table 6289. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0059#AN0162

Analytic 0126 - AN0126

Inconsistencies between process command-line arguments logged at creation time and subsequent process behavior. Defender perspective: monitoring for processes launched in a suspended state, followed by memory modifications (e.g., WriteProcessMemory targeting the PEB) that overwrite arguments before execution resumes. Detection also includes observing anomalous behaviors from processes whose logged arguments do not align with executed activity (e.g., network connections, file writes, or registry modifications).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0126 - AN0126"*

Table 6290. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0045#AN0126

Analytic 1260 - AN1260

Adversary adds federated identity provider (IdP) or modifies tenant domain authentication from Managed to Federated. Detected via API, PowerShell, or Admin Portal through federation events like `Set domain authentication`, `Add federated identity provider`, or `Update-MsolFederatedDomain`.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1260 - AN1260"*

Table 6291. Table References

https://attack.mitre.org/detectionstrategies/DET0221#AN0621

Analytic 0612 - AN0612

Detection of container escape attempts via bind mounts, privileged containers, or abuse of docker.sock. Defenders may observe anomalous volume mount configurations (e.g., hostPath to / or /proc), unexpected privileged container launches, or use of container administration commands to access host resources. These events typically correlate with subsequent process execution on the host outside of normal container isolation.

Analytic 2017 - AN2017

Once adversaries have provisioned compromised infrastructure (ex: a server for use in command and control), internet scans may help proactively discover compromised infrastructure. Consider looking for identifiable patterns such as services listening, certificates in use, SSL/TLS negotiation features, or other response artifacts associated with adversary C2 software.(Citation: ThreatConnect Infrastructure Dec 2020)(Citation: Mandiant SCANdalous Jul 2020)(Citation: Koczwara Beacon Hunting Sep 2021) Consider monitoring for anomalous changes to domain registrant information and/or domain resolution information that may indicate the compromise of a domain. Efforts may need to be tailored to specific domains of interest as benign registration and resolution changes are a common occurrence on the internet. Monitor for queried domain name system (DNS) registry data that may compromise third-party infrastructure that can be used during targeting. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Command and Control. Monitor for logged domain name system (DNS) data that may compromise third-party infrastructure that can be used during targeting. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Command and Control. Monitor for contextual data about

an Internet-facing resource gathered from a scan, such as running services or ports that may compromise third-party infrastructure that can be used during targeting. Detection efforts may be focused on related stages of the adversary lifecycle, such as during Command and Control.

Analytic 1029 - AN1029

Detection of AppCert DLL abuse involves correlating registry modifications to the AppCertDLLs key with subsequent unexpected DLL load behavior during process creation events. Specifically, defenders can observe abnormal DLLs being loaded into standard Windows processes after changes to the 'AppCertDLLs' registry value. Monitoring CreateProcess-family API executions with injected DLLs and linking those DLLs back to recent registry edits is key to identifying misuse. This is often accompanied by elevated privileges and potential lateral movement or discovery behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1029 - AN1029"*

Table 6332. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0362#AN1029

Analytic 0129 - AN0129

Execution of scripts or binaries that check for virtualization indicators (e.g., system_profiler, ioreg -l, kextstat), combined with delay functions or anomalous launchd activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0129 - AN0129"*

Table 6333. Table References

https://attack.mitre.org/detectionstrategies/DET0546#AN1503

Analytic 1305 - AN1305

Windows-specific environmental keying behavioral chain: (1) Rapid system information discovery through multiple techniques (WMI queries, registry enumeration, network share discovery, hostname/domain checks), (2) Target validation through specific environmental artifact collection (AD domain membership, network topology, installed software versions), (3) Cryptographic operation correlation indicating payload decryption based on collected environmental values, (4) Subsequent malicious code execution following successful environmental validation, (5) Temporal clustering of discovery activities suggesting automated environmental assessment

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1305 - AN1305"*

Table 6354. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0474#AN1305

Analytic 0531 - AN0531

Automated execution of native utilities and scripts to discover, enumerate, and exfiltrate files and clipboard content. Focus is on detecting repeated file access, scripting engine use, and use of command-line utilities commonly leveraged by collection scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0531 - AN0531"*

Table 6355. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0186#AN0531

Analytic 0351 - AN0351

Insertion of public keys into authorized_keys using bash/zsh or editor tools, correlated with suspicious process ancestry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0351 - AN0351"*

Table 6356. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0126#AN0351

Analytic 0315 - AN0315

Detection of changes to device startup-config files that include boot scripts or scheduled execution routines.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0315 - AN0315"*

Table 6357. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0112#AN0315

Analytic 0513 - AN0513

Process or script enumerates network shares via CLI (net view/net share, PowerShell Get-SmbShare/WMI) or OS APIs (NetShareEnum/ srvsvc.NetShareEnumAll RPC) → bursts of outbound SMB/RPC connections (445/139, \\host\IPC$ / srvsvc) to many hosts inside a short window → optional follow-on file listing or copy operations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0513 - AN0513"*

Table 6358. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0182#AN0513

Analytic 1035 - AN1035

Detects tampered hardware or firmware via anomalous host status telemetry. Behavioral chain: (1) Pre-OS or firmware components exhibit unexpected version changes, signature failures, or modified boot paths; (2) System management/firmware tools log hardware inventory drift; (3) Sensor health telemetry or boot attestation events fail baseline checks; (4) Follow-on process execution from altered firmware or unknown drivers after boot.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1035 - AN1035"*

Table 6359. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0368#AN1035

Analytic 0153 - AN0153

Detection of unauthorized modifications to Windows root certificate stores by monitoring registry keys, certificate installation processes, and creation of new certificate entries not in baseline trusted lists.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0153 - AN0153"*

Table 6360. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0056#AN0153

Analytic 1350 - AN1350

Behavioral chain: (1) delegated administration offers/relationships created or modified by partner tenants; (2) mailbox delegation/impersonation enabled; (3) follow-on access from partner IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1350 - AN1350"*

Table 6361. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0488#AN1350

Analytic 0135 - AN0135

Detects removal of Remote Login or Screen Sharing logs in Unified Logging, deletion of `com.apple.UTun`, or suspicious Terminal use of `rm`, `sudo pfctl -F all` to clear network state/config history.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0135 - AN0135"*

Table 6362. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0049#AN0135

Analytic 1530 - AN1530

Monitors for anomalous binary files written to disk with padded size and subsequent execution by user or service context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1530 - AN1530"*

Table 6363. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0553#AN1530

Analytic 1053 - AN1053

Correlate creation or modification of serverless functions (e.g., AWS Lambda, GCP Cloud Functions, Azure Functions) with anomalous IAM role assignments or permissions escalation events. Detect subsequent executions of newly created functions that perform unexpected actions such as spawning outbound network connections, accessing sensitive resources, or creating additional credentials.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1053 - AN1053"*

Table 6364. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0374#AN1053

Analytic 0613 - AN0613

Detection of Linux container escape attempts via syscalls (`unshare`, `keyctl`, `mount`) or process execution outside container namespaces. Defenders may correlate unusual system calls from containerized processes with subsequent process creation on the host or modification of host resources.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0613 - AN0613"*

Table 6365. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0219#AN0613

Analytic 1063 - AN1063

Execution of unsigned kernel extensions (KEXTs), tampering with LaunchDaemons, or userspace hooks into system libraries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1063 - AN1063"*

Table 6366. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0377#AN1063

Analytic 1036 - AN1036

Monitors for hardware or firmware tampering by correlating system boot logs, hardware inventory changes, and secure boot/firmware verification failures. Behavioral chain: (1) UEFI/BIOS version drift; (2) secure boot disabled or signature verification errors; (3) unexpected modules or hardware devices enumerated at boot; (4) new device firmware images loaded from non-approved sources.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1036 - AN1036"*

Table 6367. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0368#AN1036

Analytic 1360 - AN1360

Defenders may observe attempts to disable dedicated crypto hardware on network devices, often visible through anomalous CLI commands, unexpected firmware or configuration updates, and degraded encryption performance. Suspicious indicators include commands that alter hardware acceleration settings (e.g., disabling AES-NI or crypto engines), modification of system image files, or logs showing fallback from hardware to software encryption. Network traffic analysis may also reveal a sudden downgrade in throughput or cipher negotiation behavior consistent with the absence of hardware acceleration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1360 - AN1360"*

Table 6368. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0494#AN1360

Analytic 0163 - AN0163

Detect unauthorized manipulation of log files, database entries, or system configuration files through auditd and syslog. Correlate shell commands that alter HISTFILE or data-related processes with abnormal file access patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0163 - AN0163"*

Table 6369. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0059#AN0163

Analytic 0136 - AN0136

Detects firewall rule modifications or reset of logs/connection tables (e.g., `clear logging`, `erase startup-config`, `write erase`) following remote access activity on routers, switches, or VPN

appliances.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0136 - AN0136"*

Table 6370. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0049#AN0136

Analytic 0316 - AN0316

Detects AS-REP roasting attempts by monitoring for Kerberos AS-REQ/AS-REP authentication patterns where preauthentication is disabled (Event ID 4768 with Pre-Auth Type 0). Correlates these requests with subsequent service ticket activity (Event ID 4769) and anomalies such as requests using weak RC4 encryption (etype 0x17). Excessive enumeration of accounts with 'Do not require Kerberos preauthentication' set in Active Directory is another key detection point.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0316 - AN0316"*

Table 6371. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0113#AN0316

Analytic 0361 - AN0361

Suspicious invocation of GUI utilities or scripts with suppressed or redirected windowing options. Defender view: detection of X11 or Wayland calls to spawn windows that do not appear on active displays, or use of nohup/screen/tmux to mask interactive shells.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0361 - AN0361"*

Table 6372. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0128#AN0361

Analytic 1603 - AN1603

Detection of unauthorized changes to boot configurations pointing to TFTP servers, unusual firmware loads during netbooting, or suspicious TFTP traffic. Correlation of boot config modifications, command history logs, and unexpected system image hashes provides detection coverage for adversaries attempting to persist via malicious TFTP boot images.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1603 - AN1603"*

Table 6373. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0582#AN1603

Analytic 1306 - AN1306

Linux environmental keying behavioral chain: (1) System information gathering through native commands (uname, hostname, id, whoami, ifconfig/ip) and file system enumeration, (2) Network configuration discovery (route tables, DNS settings, network interfaces), (3) Filesystem and mount point analysis for target-specific directories or devices, (4) Process and service enumeration to identify target-specific software, (5) Cryptographic library usage correlation with collected environmental data, (6) Payload execution following successful environmental validation

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1306 - AN1306"*

Table 6374. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0474#AN1306

Analytic 1630 - AN1630

Defenders may observe adversary attempts to extract configuration data from management repositories by monitoring for anomalous SNMP queries, API calls, or protocol requests (e.g., NETCONF, RESTCONF) that enumerate system configuration. Suspicious sequences include repeated queries from untrusted IPs, abnormal query types requesting sensitive configuration data, or repository access occurring outside of normal administrative maintenance windows. Abnormal authentication attempts, sudden enumeration of device inventory, or bulk data transfer of configuration files may also be observed.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1630 - AN1630"*

Table 6375. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0592#AN1630

Analytic 0631 - AN0631

Detects when a script or binary is named with misleading or benign-looking extensions (.jpg, .doc) and is then executed via command line or a scheduled task. Includes ELF header mismatches and content-type inconsistencies on disk.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0631 - AN0631"*

Table 6376. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0226#AN0631

Analytic 1037 - AN1037

Detects tampered Mac hardware/firmware by analyzing unified logs, EndpointSecurity events, and Apple Mobile File Integrity (AMFI) checks. Behavioral chain: (1) Boot process reports firmware signature mismatch; (2) Secure Boot policy altered; (3) new EFI drivers or hardware devices appear in inventory; (4) system extension loads from unapproved developer IDs post-boot.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1037 - AN1037"*

Table 6377. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0368#AN1037

Analytic 0731 - AN0731

Analyze ESXi syslogs for management agents or VMs making outbound connections to dynamically calculated ports derived from DNS responses. Cross-check with VM traffic baselines to identify anomalies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0731 - AN0731"*

Table 6378. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0262#AN0731

Analytic 0371 - AN0371

Detects outbound traffic from hostd/vpxa or guest VM interfaces using unauthorized protocols such as FTP, HTTP POST bursts, or long-lived DNS tunnels.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0371 - AN0371"*

Table 6379. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0131#AN0371

Analytic 0137 - AN0137

An adversary writes or drops a malicious Office Add-in (e.g., WLL, XLL, COM) to a trusted directory or modifies registry keys to load malicious add-ins on Office application launch. Upon user opening Word or Excel, the add-in is automatically loaded, triggering execution of the payload, often spawning scripting engines or anomalous child processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0137 - AN0137"*

Table 6380. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0050#AN0137

Analytic 0317 - AN0317

Detects attempts to enumerate local groups via Net.exe, PowerShell, or native API calls that precede lateral movement or privilege abuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0317 - AN0317"*

Table 6381. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0114#AN0317

Analytic 1307 - AN1307

macOS environmental keying behavioral chain: (1) System information discovery through native utilities (system_profiler, sw_vers, hostname, dscl) and Security framework queries, (2) Hardware and software enumeration including serial numbers, installed applications, and system versions, (3) Network configuration assessment (networksetup, scutil) and wireless network discovery, (4) Keychain and security context validation, (5) Unified Logs correlation with cryptographic framework usage (CommonCrypto, Security.framework), (6) Application bundle execution following environmental validation

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1307 - AN1307"*

Table 6382. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0474#AN1307

Analytic 0173 - AN0173

Detects native Python or framework-based execution from Terminal, embedded apps, or launchd jobs. Flags network calls, persistence writes, or system enumeration after Python launch.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0173 - AN0173"*

Table 6383. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0063#AN0173

Analytic 1370 - AN1370

Detection of adversaries attempting to stop or disable host-based security agents by killing daemons, unloading kernel modules, or modifying init/systemd service configurations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1370 - AN1370"*

Table 6384. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0497#AN1370

Analytic 1073 - AN1073

Collection of device configuration via CLI commands (e.g., `show running-config`, `copy flash`, `more`), often followed by TFTP/SCP transfers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1073 - AN1073"*

Table 6385. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0380#AN1073

Analytic 0713 - AN0713

Defender observes unauthorized modification or creation of Python hook files such as `.pth`, `sitecustomize.py`, or `usercustomize.py` in Python `site-packages`, `dist-packages`, or user paths. This is often correlated with subsequent unexpected interpreter execution (e.g., python3 running without user interaction), changes in interpreter behavior (e.g., malicious imports), and outbound connections initiated from Python. Defender links write/modify actions on hook files with execve of python process and/or anomalous child process or network activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0713 - AN0713"*

Table 6386. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0258#AN0713

Analytic 1703 - AN1703

Application vetting services could look for misuse of dynamic libraries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1703 - AN1703"*

Table 6387. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0632#AN1703

Analytic 1730 - AN1730

This behavior is seamless to the user and is typically undetectable.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1730 - AN1730"*

Table 6388. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0649#AN1730

Analytic 1308 - AN1308

Detects rundll32.exe invoked with atypical arguments (.dll, .cpl, javascript:, mshtml). DLLs not normally loaded by rundll32 are mapped into memory. Control_RunDLL or RunHTMLApplication invoked. Suspicious DLLs or scripts accessed from disk or network. Rundll32 reaches out to external domains (e.g., fetching .sct or .hta).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1308 - AN1308"*

Table 6389. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0475#AN1308

Analytic 0381 - AN0381

Detects email-sending behavior via Terminal, AppleScript, or Automator that interfaces with SMTP or IMAP, typically using curl or mail-related APIs in unsanctioned contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0381 - AN0381"*

Table 6390. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0135#AN0381

Analytic 1083 - AN1083

Detects BusyBox or Ash shell execution from unauthorized logins or remote connections. Focus is on rare shell invocations from DCUI, SSH sessions, or remote management paths. Also watches for payload droppers or persistence artifacts using shell.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1083 - AN1083"*

Table 6391. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0384#AN1083

Analytic 0813 - AN0813

Execution of renamed or dropped files with a trailing space to deceive users or analysts, especially in LaunchAgents or LaunchDaemons.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0813 - AN0813"*

Table 6392. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0292#AN0813

Analytic 0138 - AN0138

Malicious Office add-ins loaded via VSTO, COM, or VBA auto-load paths. Upon launch of Word/Excel/Outlook, the add-in executes code without user action. Add-in resides in trusted directory or registered via Office COM/VBE subsystem. Behavior includes unsigned add-in execution, anomalous load context, or add-in spawning interpreter process.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0138 - AN0138"*

Table 6393. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0050#AN0138

Analytic 0318 - AN0318

Detects enumeration of local groups using common binaries (groups, getent, cat /etc/group) or scripting with suspicious lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0318 - AN0318"*

Table 6394. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0114#AN0318

Analytic 1380 - AN1380

Privileged or rarely used accounts performing bulk access to SharePoint files or metadata over a short time window, indicating potential scripted collection of sensitive internal documents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1380 - AN1380"*

Table 6395. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0500#AN1380

Analytic 0183 - AN0183

Use of nohup, disown, or AppleScript constructs to suppress process interrupts. Defender perspective: commands containing nohup or hidden background tasks (`osascript` with persistent execution) correlated with processes surviving user logouts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0183 - AN0183"*

Table 6396. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0067#AN0183

Analytic 1038 - AN1038

Correlate file modifications in shell startup scripts (e.g., .bashrc, .profile) with embedded `trap` commands and observe if those changes are followed by the unexpected execution of child processes when terminal signals (e.g., SIGINT) are triggered. Use contextual linking with user session activity to detect privilege misuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1038 - AN1038"*

Table 6397. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0369#AN1038

Analytic 0831 - AN0831

Detects adversarial archiving using built-in or third-party utilities (makecab, diantz, xcopy, certutil, 7z, WinRAR, WinZip). Correlates suspicious process creation events with command-line arguments for compression/encoding, followed by creation of archive files (.cab, .zip, .7z, .rar). Identifies anomalous loading of crypt32.dll for encryption operations or execution of diantz.exe to compress remotely staged files.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0831 - AN0831"*

Table 6398. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0298#AN0831

Analytic 1803 - AN1803

Mobile security products can often alert the user if their device is vulnerable to known exploits.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1803 - AN1803"*

Table 6399. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0691#AN1803

Analytic 1830 - AN1830

Scheduling tasks/jobs can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1830 - AN1830"*

Table 6400. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0707#AN1830

Analytic 1093 - AN1093

Detects anomalous ARP cache changes and unsolicited ARP broadcasts using unified logs and packet capture. Behavioral detection includes multiple IP addresses mapped to the same MAC address and repeated gratuitous ARP traffic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1093 - AN1093"*

Table 6401. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0387#AN1093

Analytic 0913 - AN0913

Detects the presence of executables with high NOP padding, unusually large binary size for their function, and follow-on execution or memory injection from such files, especially when originating from temp or user-space paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0913 - AN0913"*

Table 6402. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0322#AN0913

Analytic 0193 - AN0193

Phishing delivered via SaaS services (chat, collaboration platforms) where messages contain malicious URLs or attachments. Detect anomalous link clicks, suspicious file uploads, or token misuse after SaaS-based phishing attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0193 - AN0193"*

Table 6403. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0070#AN0193

Analytic 1309 - AN1309

Correlates creation of email forwarding rules or header anomalies (e.g., X-MS-Exchange-Organization-AutoForwarded) with suspicious process execution, file access of .pst/.ost files, and network connections to external SMTP servers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1309 - AN1309"*

Table 6404. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0476#AN1309

Analytic 0139 - AN0139

Creation or modification of files in directories known to be excluded from AV scanning (e.g., C:\Windows\Temp, Exchange server directories, or default AV exclusions). Defender perspective: correlate file creation with execution behavior or anomalous parent processes writing to excluded paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0139 - AN0139"*

Table 6405. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0051#AN0139

Analytic 0931 - AN0931

Remote Desktop (RDP) logon by a user followed by unusual process execution, file access, or lateral movement activity within a short timeframe.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0931 - AN0931"*

Table 6406. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0327#AN0931

Analytic 0319 - AN0319

Detects use of dscl or id/group commands to enumerate local system groups, often by post-exploitation tools or persistence checks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0319 - AN0319"*

Table 6407. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0114#AN0319

Analytic 1039 - AN1039

Detect unauthorized `trap` command registrations in shell startup files (e.g., .zprofile, .bash_profile, .zshrc) followed by execution chains during user terminal interaction. Use Unified Logs and EDR telemetry to correlate shell command parsing and process tree anomalies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1039 - AN1039"*

Table 6408. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0369#AN1039

Analytic 0391 - AN0391

Detects DYLD_INSERT_LIBRARIES abuse to hook credential-sensitive applications by correlating process spawns with unauthorized library injection and monitoring changes to the __TEXT segment (code) of credential handling binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0391 - AN0391"*

Table 6409. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0139#AN0391

Analytic 1390 - AN1390

Detects command-line utilities or scripts using encryption libraries or symmetric algorithms (e.g., OpenSSL AES, GPG, Python + PyCrypto) in conjunction with outbound file transfers or traffic to external destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1390 - AN1390"*

Table 6410. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0503#AN1390

Analytic 1404 - AN1404

Detects unauthorized access to browser cookie paths (e.g., `~/Library/Application Support/Google/Chrome/Default/Cookies`) or `task_for_pid`/`vm_read` calls to Safari/Chrome memory space.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1404 - AN1404"*

Table 6411. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0509#AN1404

Analytic 0144 - AN0144

Detects excessive outbound traffic to remote host over HTTP(S) from uncommon or previously unseen processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0144 - AN0144"*

Table 6412. Table References

Analytic 0481 - AN0481

Defenders should monitor for suspicious enumeration of cloud infrastructure components via APIs or CLI tools. Observable behaviors include repeated listing or description operations for compute instances, snapshots, storage buckets, and volumes. From a defender's perspective, risky activity is often identified by new or untrusted identities making discovery calls (e.g., DescribeInstances, ListBuckets, az vm list, gcloud compute instances list), enumeration from unusual geolocations or IPs, or rapid multi-service discovery in sequence. Correlating discovery API usage with later snapshot creation or instance modification provides further context of adversary behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0481 - AN0481"*

Table 6461. Table References

https://attack.mitre.org/detectionstrategies/DET0372#AN1049

Analytic 0914 - AN0914

Detects ELF binaries written to disk that demonstrate anomalous file size or entropy, quickly followed by execution or memory region writes into remote processes (e.g., using ptrace).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0914 - AN0914"*

Table 6474. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0322#AN0914

Analytic 1409 - AN1409

Detects SVGs downloaded via browser that invoke AppleScript, osascript, or JavaScriptCore processes, followed by network egress or file drop to LaunchAgents or ~/Library.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1409 - AN1409"*

Table 6475. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0510#AN1409

Analytic 0155 - AN0155

Detection of malicious certificate installation via monitoring execution of the `security add-trusted-cert` command and modifications to system keychains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0155 - AN0155"*

Table 6476. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0056#AN0155

Analytic 0515 - AN0515

Use of native/mac tools (sharing -l, smbutil view, mount_smbfs) or scripts to enumerate SMB shares across many hosts, followed by outbound SMB connections observed in PF/Zeek logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0515 - AN0515"*

Table 6477. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0182#AN0515

Analytic 1550 - AN1550

Adversary adds IDE extensions or plugins (VS Code, JetBrains Toolbox/EAP, Eclipse) via GUI or CLI, possibly via managed profiles. Chain: process start with install/update flags → plist/extension folder changes under ~/Library/Application Support/Code or ~/Library/Application Support/JetBrains → outbound connections to marketplaces/tunnel services → optional helper (ssh/node) spawned.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1550 - AN1550"*

Table 6478. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0561#AN1550

Analytic 1055 - AN1055

Track creation or update of SaaS automation scripts (e.g., Google Workspace Apps Script). Detect when these scripts are bound to user events such as file opens or account modifications, and correlate with subsequent abnormal API calls that exfiltrate or modify user data.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1055 - AN1055"*

Table 6479. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0374#AN1055

Analytic 0551 - AN0551

Suspicious creation or modification of inbox rules through PowerShell (New-InboxRule, Set-InboxRule) to automatically delete, move, or hide emails. Defender perspective: unusual rule activity correlated with mailbox access and filtering patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0551 - AN0551"*

Table 6480. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0192#AN0551

Analytic 1505 - AN1505

Detects unexpected access or usage of cloud productivity tools (e.g., downloading large numbers of files, creating external shares) by internal users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1505 - AN1505"*

Table 6481. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0546#AN1505

Analytic 1065 - AN1065

Detects use of gzip, base64, tar, or openssl in scripts or commands that encode/encrypt files after file staging or system enumeration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1065 - AN1065"*

Table 6482. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0378#AN1065

Analytic 1560 - AN1560

Processes executing binaries named after legitimate system utilities (e.g., net.exe, findstr.exe, python.exe) from non-standard or application-specific directories, combined with file creation or modification events for such binaries. Defender correlates file writes in vulnerable directories, process execution paths inconsistent with baseline system paths, and abnormal parent-child relationships in process lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1560 - AN1560"*

Table 6483. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0564#AN1560

Analytic 1506 - AN1506

Detects login and usage patterns deviating from typical Microsoft 365 or Google Workspace user profiles.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1506 - AN1506"*

Table 6484. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0546#AN1506

Analytic 0561 - AN0561

Execution of `ifconfig`, `networksetup`, or `system_profiler` to query IP/MAC/interface configuration and status.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0561 - AN0561"*

Table 6485. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0195#AN0561

Analytic 0156 - AN0156

Detects suspicious memory access attempts targeting the `securityd` process. Observes tools invoking process memory read operations (e.g., ptrace, task_for_pid) against `securityd`. Correlates with anomalous parent process lineage, root privilege escalation, or repeated unauthorized attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0156 - AN0156"*

Table 6486. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0057#AN0156

Analytic 1605 - AN1605

Adversary invokes 'useradd', 'adduser', or equivalent system commands or scripts to create local users. Detection focuses on command execution and audit trail of passwd/shadow file modifications.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1605 - AN1605"*

Table 6487. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0583#AN1605

Analytic 0615 - AN0615

Detection of ESXi escape attempts by monitoring for anomalies in hypervisor logs such as unexpected VM operations, privilege escalation events, or attempts to load malicious kernel modules within the hypervisor environment.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0615 - AN0615"*

Table 6488. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0219#AN0615

Analytic 1056 - AN1056

Monitor for creation or modification of udev rules files in key directories (/etc/udev/rules.d/, /lib/udev/rules.d/, /usr/lib/udev/rules.d/). Look for RUN+= or IMPORT keys invoking suspicious binaries or scripts. Correlate this with process execution from systemd-udevd context, and file writes near udev reload/restart events. Combine this with unexpected background process spawning from udevd-related forks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1056 - AN1056"*

Table 6489. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0375#AN1056

Analytic 0516 - AN0516

Correlate suspicious file transfers over SMB or Admin$ shares with process creation events (e.g., cmd.exe, powershell.exe, certutil.exe) that do not align with normal administrative behavior. Detect remote file writes followed by execution of transferred binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0516 - AN0516"*

Table 6490. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0183#AN0516

Analytic 0651 - AN0651

Detect the creation or modification of common media file formats (e.g., .jpg, .png, .wav) following suspicious process activity like compression or encryption, especially when paired with lateral movement or exfiltration behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0651 - AN0651"*

Table 6491. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0235#AN0651

Analytic 0165 - AN0165

Unusual or uncommon processes initiate network connections to external destinations followed by file creation (tools downloaded).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0165 - AN0165"*

Table 6492. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0060#AN0165

Analytic 1650 - AN1650

Application vetting services could look for `android.permission.READ_CALL_LOG` in an Android application's manifest. Most applications do not need call log access, so extra scrutiny could be applied to those that request it. On Android, the user can manage which applications have permission to access the call log through the device settings screen, revoking the permission if necessary.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1650 - AN1650"*

Table 6493. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0602#AN1650

Analytic 0517 - AN0517

Monitor scp, rsync, curl, sftp, or ftp processes initiating transfers to internal systems combined with file creation events in unusual directories. Correlate transfer activity with subsequent execution of those binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0517 - AN0517"*

Table 6494. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0183#AN0517

Analytic 0571 - AN0571

Detection correlates anomalous Docker or Kubernetes API requests with access to logs, secrets, or service accounts. Observes unauthorized use of `docker logs`, `kubectl get secrets`, or direct API calls to Kubernetes API server endpoints. Identifies behavioral patterns where adversaries escalate from basic pod/container interaction to privileged API calls exposing sensitive credential material.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0571 - AN0571"*

Table 6495. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0198#AN0571

Analytic 1570 - AN1570

Defenders may observe adversary attempts to downgrade system images by monitoring for anomalous file transfers of OS image files (via TFTP, FTP, SCP), configuration changes pointing boot system variables to older image files, unexpected OS version strings after reboot, and checksum mismatches against approved baseline images. Suspicious chains include transfer of an older image, alteration of boot configuration, and reboot/reload of the device. Adversaries may also tamper with CLI output to disguise downgrade attempts, requiring independent validation of OS version and integrity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1570 - AN1570"*

Table 6496. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0569#AN1570

Analytic 0715 - AN0715

Execution of known or custom VNC/remote desktop daemons or tunneling agents that initiate external communication after launch

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0715 - AN0715"*

Table 6497. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0259#AN0715

Analytic 1057 - AN1057

Detects processes performing network enumeration (e.g., port scans, service probing) by correlating process creation, socket connections, and sequential destination IP probing within a time window.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1057 - AN1057"*

Table 6498. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0376#AN1057

Analytic 0157 - AN0157

Detects adversaries attempting to attach debuggers or memory dump utilities to credential storage daemons analogous to macOS `securityd`. Observes ptrace syscalls, /proc/<pid>/mem access, or gcore dumps against sensitive processes. Correlates anomalies with privilege escalation or credential dumping attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0157 - AN0157"*

Table 6499. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0057#AN0157

Analytic 0751 - AN0751

SSH session from new source IP followed by interactive shell or privilege escalation (e.g., sudo, su) and outbound lateral connection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0751 - AN0751"*

Table 6500. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0269#AN0751

Analytic 0175 - AN0175

Detects Python script or interpreter execution on ESXi hosts via embedded BusyBox shells, nested installations, or dropped files via SSH or datastore mount. Flags unusual scripting or post-compromise enumeration behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0175 - AN0175"*

Table 6501. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0063#AN0175

Analytic 1075 - AN1075

Correlates file enumeration of XML files in the SYSVOL share with suspicious process execution that decodes or reads encrypted credentials embedded in Group Policy Preference files (e.g., Get-GPPPassword.ps1, gpprefdecrypt.py, Metasploit). Detects abnormal access to \DOMAIN\SYSVOL combined with XML file parsing or decryption logic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1075 - AN1075"*

Table 6502. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0381#AN1075

Analytic 1507 - AN1507

Installation of malicious IIS/Apache/SQL server modules that later execute command-line interpreters or establish outbound connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1507 - AN1507"*

Table 6503. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0547#AN1507

Analytic 1705 - AN1705

Application vetting services may be able to detect known privilege escalation exploits contained within applications, as well as searching application packages for strings that correlate to known password store locations. Mobile security products can potentially detect jailbroken devices.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1705 - AN1705"*

Table 6504. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0633#AN1705

Analytic 1750 - AN1750

Application vetting services could look for use of standard APIs (e.g. the clipboard API) that could indicate data manipulation is occurring.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1750 - AN1750"*

Table 6505. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0660#AN1750

Analytic 1085 - AN1085

A process outside of interactive shell context reads ~/.bash_history directly (e.g., using cat, less, grep), often shortly after privilege escalation or user switch (su/sudo). This may be followed by credential scanning in memory or file writes to new locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1085 - AN1085"*

Table 6506. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0385#AN1085

Analytic 1058 - AN1058

Detects use of network scanning utilities or scripts performing rapid connections to multiple services or hosts using auditd and netflow/pcap telemetry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1058 - AN1058"*

Table 6507. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0376#AN1058

Analytic 0851 - AN0851

User or remote input triggers application crash or segmentation fault (e.g., SIGSEGV) with service recovery attempts, observed via audit logs and systemd journaling.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0851 - AN0851"*

Table 6508. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0304#AN0851

Analytic 0518 - AN0518

Detect anomalous use of scp, rsync, curl, or third-party sync apps transferring executables into user directories. Correlate new file creation with immediate execution events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0518 - AN0518"*

Table 6509. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0183#AN0518

Analytic 1580 - AN1580

Detects snapshot sharing, backup exports, or data object transfers from victim-owned cloud accounts to other cloud identities within the same provider (e.g., AWS, Azure) using snapshot sharing, S3 bucket policy updates, or SAS URI generation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1580 - AN1580"*

Table 6510. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0573#AN1580

Analytic 0158 - AN0158

Detection of a process or script that accesses a common web service to retrieve content containing obfuscated indicators of a secondary C2 server (dead drop resolver behavior).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0158 - AN0158"*

Table 6511. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0058#AN0158

Analytic 0185 - AN0185

Chain: (1) a new external device is recognized by Windows (USB/Thunderbolt/PCIe) or a new block device appears; (2) within a short window, the same user/session spawns processes or the OS mounts a new volume; (3) optional follow-on activity such as HID keystroke injection, DMA driver load, or new network interface MAC on DHCP. Correlate Security EID 6416 / Kernel-PnP with sysmon and DHCP/network metadata.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0185 - AN0185"*

Table 6512. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0069#AN0185

Analytic 1508 - AN1508

Abuse of extensible server modules (e.g., Apache, Nginx, Tomcat) to load rogue plugins that initiate bash, connect to C2, or spawn reverse shells.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1508 - AN1508"*

Table 6513. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0547#AN1508

Analytic 0815 - AN0815

Detects registration of new PTA agents, conditional access changes disabling hybrid MFA enforcement, or suspicious updates to AD FS token-signing configurations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0815 - AN0815"*

Table 6514. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0293#AN0815

Analytic 0581 - AN0581

Execution of XSL scripts via msxsl.exe or wmic.exe using embedded JScript or VBScript for proxy execution. Detection correlates process creation, command-line patterns, and module load behavior of scripting components (e.g., jscript.dll).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0581 - AN0581"*

Table 6515. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0205#AN0581

Analytic 1805 - AN1805

Mobile security products can typically detect rooted devices, which is an indication that Process Discovery is possible. Application vetting could potentially detect when applications attempt to abuse root access or root the system itself. Further, application vetting services could look for attempted usage of legacy process discovery mechanisms, such as the usage of `ps` or inspection of the `/proc` directory.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1805 - AN1805"*

Table 6516. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0692#AN1805

Analytic 1850 - AN1850

Hooking can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1850 - AN1850"*

Table 6517. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0719#AN1850

Analytic 0195 - AN0195

Detects inbound SCP, rsync, or NFS mounts from remote systems followed by aggregation of files into known staging paths like /mnt/staging or /var/tmp.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0195 - AN0195"*

Table 6518. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0071#AN0195

Analytic 1059 - AN1059

Detects Bonjour-based mDNS enumeration or use of system tools (e.g., dns-sd, nmap) to find active services via multicast probing or targeted scans.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1059 - AN1059"*

Table 6519. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0376#AN1059

Analytic 0591 - AN0591

Use of domain accounts via sssd or winbind for logon activity outside of typical patterns, especially on sensitive systems or with lateral movement tools.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0591 - AN0591"*

Table 6520. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0210#AN0591

Analytic 1950 - AN1950

Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders.

Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1950 - AN1950"*

Table 6521. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0818#AN1950

Analytic 0951 - AN0951

Monitors binary modification in /Applications and system library paths. Detects unsigned or improperly signed binaries executed after modification. Tracks Gatekeeper or notarization bypass attempts tied to modified binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0951 - AN0951"*

Table 6522. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0336#AN0951

Analytic 1095 - AN1095

Detects DLL injection through correlation of memory allocation and writing to remote process memory (e.g., VirtualAllocEx, WriteProcessMemory), followed by remote thread creation (e.g., CreateRemoteThread) that loads a suspicious or unsigned DLL using LoadLibrary or reflective loading.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1095 - AN1095"*

Table 6523. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0389#AN1095

Analytic 1590 - AN1590

Creation or modification of Apple Mail rules by accessing plist files or GUI automation (AppleScript).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1590 - AN1590"*

Table 6524. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0576#AN1590

Analytic 1509 - AN1509

Malicious use of webserver plugins (e.g., for nginx, PHP, Node.js) that execute AppleScript or open network sockets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1509 - AN1509"*

Table 6525. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0547#AN1509

Analytic 0159 - AN0159

Detection of a process or script that accesses a common web service to retrieve content containing obfuscated indicators of a secondary C2 server (dead drop resolver behavior).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0159 - AN0159"*

Table 6526. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0058#AN0159

Analytic 0519 - AN0519

Identify lateral transfer via datastore file uploads or internal scp/ssh sessions that result in new VMX/VMDK or script files. Correlate transfer with VM execution or datastore modification.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0519 - AN0519"*

Table 6527. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0183#AN0519

Analytic 0915 - AN0915

Identifies Mach-O binaries dropped into temporary directories with abnormally high binary size or padding patterns, followed by privilege escalation, `exec`, or memory mapping of other processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0915 - AN0915"*

Table 6528. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0322#AN0915

Analytic 1066 - AN1066

Monitors use of archive or encryption tools (zip, openssl) tied to user-scripted activity or binaries writing encoded payloads under /Users or /Volumes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1066 - AN1066"*

Table 6529. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0378#AN1066

Analytic 0166 - AN0166

Shell-based tools (curl, wget, scp) initiate connections to external domains followed by creation of executable files on disk.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0166 - AN0166"*

Table 6530. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0060#AN0166

Analytic 0616 - AN0616

Detects USB device insertion followed by high-volume or sensitive file access and staging activity by suspicious processes or accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0616 - AN0616"*

Table 6531. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0220#AN0616

Analytic 0661 - AN0661

Detection of modified boot-time configuration scripts that persist malicious CLI commands across reboots.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0661 - AN0661"*

Table 6532. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0237#AN0661

Analytic 1606 - AN1606

Adversary creates new users using 'dscl' commands, GUI tools, or by modifying user plist files. Detection includes monitoring dscl invocation and user-related plist changes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1606 - AN1606"*

Table 6533. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0583#AN1606

Analytic 1660 - AN1660

On Android, the user can review which applications can use premium SMS features in the "Special access" page within application settings. Application vetting services can detect when applications request the `SEND_SMS` permission, which should be infrequently used.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1660 - AN1660"*

Table 6534. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0608#AN1660

Analytic 0716 - AN0716

Initiation of remote desktop sessions via AnyDesk, TeamViewer, or Chrome Remote Desktop accompanied by unexpected user logins or system modifications

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0716 - AN0716"*

Table 6535. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0259#AN0716

Analytic 0167 - AN0167

Process execution of curl or wget followed by a network connection and a file created in temporary or user-specific directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0167 - AN0167"*

Table 6536. Table References

https://attack.mitre.org/detectionstrategies/DET0060#AN0167

Analytic 1607 - AN1607

Adversary creates users via IAM/IdP API or portal (e.g., Azure AD, Okta). Detection involves monitoring API calls, admin action logs, and correlation with role assignments.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1607 - AN1607"*

Table 6537. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0583#AN1607

Analytic 0761 - AN0761

Applications or launchd jobs initiating encrypted TLS traffic to rare external hosts. Defender observes unified logs showing ssl/TLS API calls by processes not baseline-approved, and payload entropy suggesting encrypted C2 sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0761 - AN0761"*

Table 6538. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0273#AN0761

Analytic 1067 - AN1067

Identifies transfer of base64, uuencoded, or high-entropy files over HTTP, FTP, or custom protocols in lateral movement or exfiltration streams.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1067 - AN1067"*

Table 6539. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0378#AN1067

Analytic 0617 - AN0617

Detects USB block device mount followed by file access in sensitive directories or high-volume copy operations by user-controlled processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0617 - AN0617"*

Table 6540. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0220#AN0617

Analytic 0176 - AN0176

Unquoted service or shortcut paths that contain spaces and allow path interception by higher-level executables. Defender observes registry service configurations with unquoted paths, file creation of

executables in parent directories of unquoted paths, and subsequent process execution from unexpected locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0176 - AN0176"*

Table 6541. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0064#AN0176

Analytic 1076 - AN1076

Detects adversary use of suspended process creation, using the CREATE_SUSPENDED flag via CreateProcess, followed by unmapping the memory of the child process (NtUnmapViewOfSection) and replacing it with malicious code via VirtualAllocEx/WriteProcessMemory, then SetThreadContext and ResumeThread to begin execution within the hollowed process.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1076 - AN1076"*

Table 6542. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0382#AN1076

Analytic 0671 - AN0671

Monitor for abnormal certificate enrollment and usage activity in Active Directory Certificate Services (AD CS), registry access to certificate storage locations, and unusual process executions that attempt to export or access private keys.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0671 - AN0671"*

Table 6543. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0240#AN0671

Analytic 1760 - AN1760

Mobile security products can often alert the user if their device is vulnerable to known exploits.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1760 - AN1760"*

Table 6544. Table References

https://attack.mitre.org/detectionstrategies/DET0666#AN1760

Analytic 1670 - AN1670

Mobile security products can often alert the user if their device is vulnerable to known exploits.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1670 - AN1670"*

Table 6545. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0614#AN1670

Analytic 1706 - AN1706

Application vetting services could look for usage of the `READ_PRIVILEGED_PHONE_STATE` Android permission. This could indicate that non-system apps are attempting to access information that they do not have access to.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1706 - AN1706"*

Table 6546. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0634#AN1706

Analytic 0816 - AN0816

Detects API calls registering or updating hybrid identity connectors, modification of cloud-to-on-premises federation trust, and unusual token issuance logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0816 - AN0816"*

Table 6547. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0293#AN0816

Analytic 0186 - AN0186

Chain: (1) udev / kernel logs show hot-plug (USB/Thunderbolt/PCIe); (2) block device created by udisks/diskarbitration; (3) optional: new network interface or DHCP lease observed. Correlate /var/log/messages|syslog, auditd SYSCALL open/creat on /dev, and DHCP/Zeek.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0186 - AN0186"*

Table 6548. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0069#AN0186

Analytic 0618 - AN0618

Detects external volume mount with Finder, Terminal, or script-initiated file copy from user profiles, sensitive folders, or cloud storage sync directories to USB.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0618 - AN0618"*

Table 6549. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0220#AN0618

Analytic 0681 - AN0681

Defenders may observe attempts to alter cryptographic settings on network devices that reduce key strength or allowable cipher suites. Suspicious indicators include configuration changes that downgrade encryption algorithms, key length parameters, or the disabling of strong encryption in favor of legacy ciphers. These activities often appear as CLI commands modifying crypto policies, firmware changes affecting crypto libraries, or unexpected updates to key management files. Correlation across device config logs and traffic analysis showing weaker ciphers provides higher confidence of malicious key space reduction.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0681 - AN0681"*

Table 6550. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0243#AN0681

Analytic 0861 - AN0861

Detection focuses on identifying unauthorized or anomalous changes to compute infrastructure components. Defender perspective: monitor for creation, deletion, or modification of instances, volumes, and snapshots outside of approved change management windows; correlate abnormal activity such as rapid snapshot creation followed by new instance mounts, or repeated infrastructure changes by rarely used accounts. Flagging activity linked to unusual geolocation, API client, or automation script is suspicious.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0861 - AN0861"*

Table 6551. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0308#AN0861

Analytic 1608 - AN1608

Account creation via cloud service APIs or CLI, often associated with key generation. Monitored via

CloudTrail or equivalent audit logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1608 - AN1608"*

Table 6552. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0583#AN1608

Analytic 1086 - AN1086

A process or terminal command outside of standard shell utilities reads the user's .bash_history file. On macOS, unified logs or telemetry tools like EndpointSecurity (ESF) may observe file read APIs or terminal process lineage that shows non-user-initiated access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1086 - AN1086"*

Table 6553. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0385#AN1086

Analytic 1068 - AN1068

Detects encoded PowerCLI or Base64-encoded payloads staged via datastore uploads or shell access (e.g., ESXi Shell or backdoored VIBs).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1068 - AN1068"*

Table 6554. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0378#AN1068

Analytic 0168 - AN0168

Command line interface or vCLI triggers remote transfer using wget or curl, writing files into datastore paths or local tmp directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0168 - AN0168"*

Table 6555. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0060#AN0168

Analytic 1806 - AN1806

The user can view a list of active device administrators in the device settings.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1806 - AN1806"*

Table 6556. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0693#AN1806

Analytic 1680 - AN1680

On Android, the user can use the device settings menu to view trusted CA certificates and look for unexpected or unknown certificates. A mobile security product could similarly examine the trusted CA certificate store for anomalies. Users can use the device settings menu to view which applications on the device are allowed to install unknown applications.

On iOS, the user can use the device settings menu to view installed Configuration Profiles and look for unexpected or unknown profiles. A Mobile Device Management (MDM) system could use the iOS MDM APIs to examine the list of installed Configuration Profiles for anomalies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1680 - AN1680"*

Table 6557. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0619#AN1680

Analytic 1960 - AN1960

Much of this activity may have a very high occurrence and associated false positive rate, as well as potentially taking place outside the visibility of the target organization, making detection difficult for defenders.

Detection efforts may be focused on related stages of the adversary lifecycle, such as during Initial Access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1960 - AN1960"*

Table 6558. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0828#AN1960

Analytic 0196 - AN0196

Detects rsync or scp inbound from other hosts that then aggregate content into /Users/Shared or

/private/tmp, often involving compressed files or scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0196 - AN0196"*

Table 6559. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0071#AN0196

Analytic 0691 - AN0691

CONTAINERS (Docker/K8s/containerd): A user pulls an untrusted image from a public/unknown registry and then creates/starts a container from that image. Shortly after start, the container spawns unexpected utilities (e.g., curl/wget/bash/python), or makes outbound network connections atypical for the namespace/workload. The analytic correlates Image Creation/Download → Container Creation → Container Start → Command Execution/Network activity within a short window and with a consistent image digest.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0691 - AN0691"*

Table 6560. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0248#AN0691

Analytic 0619 - AN0619

Unusual or unauthorized processes accessing microphone APIs (e.g., winmm.dll, avrt.dll) followed by audio file writes to user-accessible or temp directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0619 - AN0619"*

Table 6561. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0221#AN0619

Analytic 1609 - AN1609

Unexpected creation or modification of files with `com.apple.ResourceFork` extended attributes containing unusually large or non-standard data. Defender perspective: detection of resource forks in contexts where they are uncommon, especially when paired with process execution or network activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1609 - AN1609"*

Table 6562. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0584#AN1609

Analytic 1069 - AN1069

Detects rogue Wi-Fi access points broadcasting the same SSID as legitimate APs with stronger signal strength, unexpected MAC/BSSID values, or inconsistent encryption settings. Correlates authentication attempts, captive portal redirections, and anomalous traffic flows through unauthorized APs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1069 - AN1069"*

Table 6563. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0379#AN1069

Analytic 0916 - AN0916

Detection of anomalous driver and firmware interactions, including unsigned or unexpected firmware updates, driver loads linked to hardware components, and suspicious use of privileged APIs to read/write firmware or controller memory.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0916 - AN0916"*

Table 6564. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0323#AN0916

Analytic 1096 - AN1096

Correlation of file creation/modification of `.desktop` files within XDG autostart directories, followed by execution of processes at user login initiated by the desktop environment. Malicious entries typically include suspicious Exec paths or anomalous names and are not associated with installed packages.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1096 - AN1096"*

Table 6565. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0390#AN1096

Analytic 0961 - AN0961

Defenders may observe unauthorized modifications to encryption-related configuration files, firmware, or crypto modules on network devices. Suspicious patterns include changes to cipher suite configurations, unexpected firmware updates affecting crypto libraries, disabling of hardware

cryptographic accelerators, or reductions in key length policies. Correlating configuration changes with anomalies in encrypted traffic characteristics (e.g., weaker ciphers or sudden plaintext transmission) strengthens detection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0961 - AN0961"*

Table 6566. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0339#AN0961

Analytic 0169 - AN0169

Network device logs show anomalous inbound file transfers or uncharacteristic flows with high payload volume to network devices with storage or automation hooks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0169 - AN0169"*

Table 6567. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0060#AN0169

Analytic 1690 - AN1690

Remote access software typically requires many privileged permissions, such as accessibility services or device administrator.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1690 - AN1690"*

Table 6568. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0624#AN1690

Analytic 0771 - AN0771

Detection of new IAM roles or policies attached to a user/service in AWS/GCP/Azure outside normal patterns or hours, often following account compromise.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0771 - AN0771"*

Table 6569. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0277#AN0771

Analytic 1077 - AN1077

Detects adversary behavior where a newly created or renamed user account closely resembles existing service or administrator accounts to blend in and avoid detection. Common patterns include prefix/suffix modifications, homoglyphs, or use of names like 'admin1', 'adm1n', or 'backup_help'.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1077 - AN1077"*

Table 6570. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0383#AN1077

Analytic 0177 - AN0177

Defenders may detect abuse of container administration commands by observing anomalous use of management utilities (`docker exec`, `kubectl exec`, or API calls to kubelet) correlated with unexpected process creation inside containers. Behavioral chains include unauthorized API requests followed by command execution within running pods or containers, often originating from unusual user accounts, automation scripts, or IP addresses outside the expected cluster management plane.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0177 - AN0177"*

Table 6571. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0065#AN0177

Analytic 0717 - AN0717

Defenders may detect adversaries forging web credentials in IaaS environments by monitoring for anomalous API activity such as AssumeRole or GetFederationToken being executed by unusual principals. These events often correlate with sudden logon sessions from unfamiliar IP addresses or regions. The chain is usually secret material misuse (stolen private key or password) → API request generating a new token → access to high-value resources.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0717 - AN0717"*

Table 6572. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0260#AN0717

Analytic 1770 - AN1770

Application vetting services may provide a list of connections made or received by an application, or a list of domains contacted by the application. Many properly configured firewalls may naturally

block command and control traffic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1770 - AN1770"*

Table 6573. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0672#AN1770

Analytic 1707 - AN1707

Application vetting services could look for usage of the `READ_PRIVILEGED_PHONE_STATE` Android permission. This could indicate that non-system apps are attempting to access information that they do not have access to.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1707 - AN1707"*

Table 6574. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0634#AN1707

Analytic 0817 - AN0817

Detects tenant-wide authentication or conditional access changes that weaken hybrid identity enforcement, including disabling AD FS or bypassing hybrid MFA policies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0817 - AN0817"*

Table 6575. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0293#AN0817

Analytic 0871 - AN0871

Multi-event correlation of Registry creation under Active Setup with anomalous execution of processes at user logon. Behavioral patterns include creation/modification of HKLM Active Setup keys with non-standard StubPath values, followed by process execution from uncommon paths, unsigned binaries, or unusual parent-child lineage post-user login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0871 - AN0871"*

Table 6576. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0312#AN0871

Analytic 0178 - AN0178

Behavioral chain: (1) a user-facing app (browser/Office/email client) launches a URL or handles a link, then (2) the same process lineage makes an outbound connection to an untrusted domain/IP, (3) a file is downloaded or unpacked to a user-writable location shortly after the click. Optional enrichment: subsequent child execution by LOLBINs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0178 - AN0178"*

Table 6577. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0066#AN0178

Analytic 0187 - AN0187

Chain: (1) unified logs report IOUSBHost/IOThunderbolt device arrival; (2) diskarbitrationd attaches a new volume; (3) optional: config profile manipulation or new network interface MAC obtains a lease. Correlate unifiedlogs (subsystems: IOUSBHost, IOKit, diskarbitrationd), FSEvents, and DHCP/Zeek.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0187 - AN0187"*

Table 6578. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0069#AN0187

Analytic 1078 - AN1078

Detects creation or renaming of accounts with names that closely match known service, root, or admin accounts. Behavior often follows account discovery or deletion, attempting to blend into system activity logs using trusted name conventions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1078 - AN1078"*

Table 6579. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0383#AN1078

Analytic 0718 - AN0718

Forged web credentials may manifest as anomalous SAML token issuance, OpenID Connect token minting, or Zimbra pre-auth key usage. Defenders may see tokens issued without normal authentication events, multiple valid tokens generated simultaneously, or signing anomalies in IdP logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0718 - AN0718"*

Table 6580. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0260#AN0718

Analytic 0781 - AN0781

Behavior chain involving abnormal registry modifications via CLI, PowerShell, WMI, or direct API calls, especially targeting persistence, privilege escalation, or defense evasion keys, potentially followed by service restart or process execution. Such as editing Notify/Userinit/Startup keys, or disabling SafeDllSearchMode.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0781 - AN0781"*

Table 6581. Table References

Process execution without GUI context (e.g., powershell.exe, wscript.exe) generates HTTP traffic with a spoofed User-Agent mimicking a legitimate browser. No corresponding UI application (e.g., msedge.exe) is active or in parent lineage. The User-Agent deviates from known enterprise baselines or contains spoofed platform indicators. User-Agent strings can be gathered with API calls such as `ShellExecuteW` to open the default browser on a socket to receive an HTTP reply, or by hard coding the User-Agent string for a specific browser.

Analytic 0472 - AN0472

Adversary registers a malicious Microsoft Exchange transport agent DLL (.NET assembly), configures it via PowerShell or Exchange Management Shell, and persists code execution by manipulating email processing logic based on rules or headers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0472 - AN0472"*

Table 6707. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0166#AN0472

Analytic 0284 - AN0284

Monitors for TCC-bypassing or unauthorized access to input services like IOHIDSystem or Quartz Event Services used in keylogging or screen monitoring.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0284 - AN0284"*

Table 6708. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0102#AN0284

Analytic 0842 - AN0842

A remote source rapidly touches a short sequence of closed ports (SYN→RST/S0) on a Windows host. Within a short window the host changes firewall state (WFP rule added/modified or service starts listening) and then the same source completes the first successful handshake to the newly opened port.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0842 - AN0842"*

Table 6709. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0302#AN0842

Analytic 0824 - AN0824

Detects unauthorized edits to /etc/hosts, /etc/resolv.conf, or suspicious ARP broadcasts. Correlates file modifications with subsequent unexpected network sessions or service creation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0824 - AN0824"*

Table 6710. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0296#AN0824

Analytic 0248 - AN0248

Detection of file write-access to USB-mount directories (e.g., /media/, /run/media/) followed by same-file access or execution on another host.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0248 - AN0248"*

Table 6711. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0090#AN0248

Analytic 0428 - AN0428

Detection of raw access to physical drives, modification of boot records (MBR/VBR), and suspicious file creation or alteration within the EFI System Partition (ESP). Correlates privileged process execution with low-level disk modification and unexpected driver or firmware interactions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0428 - AN0428"*

Table 6712. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0150#AN0428

Analytic 0482 - AN0482

Defenders may observe adversary attempts to alter or replace a network device's operating system image through anomalous CLI commands, unexpected firmware updates, integrity check failures, or mismatches in version and checksum validation. Suspicious behavior includes modification of image files on storage, OS version output inconsistent with baselines, unexpected reloads or reboots after image replacement, and changes to boot configuration that load non-standard system images.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0482 - AN0482"*

Table 6713. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0170#AN0482

Analytic 0294 - AN0294

Unsigned or scripting-based processes invoking password cracking binaries or accessing hashed credential artifacts post-login

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0294 - AN0294"*

Table 6714. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0105#AN0294

Analytic 0429 - AN0429

Detection of suspicious write operations to block devices, modifications of bootloader files (GRUB, initrd, vmlinuz), and unexpected changes within the EFI System Partition. Monitors privileged execution of utilities like dd, grub-install, or efibootmgr that modify boot sectors or loader entries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0429 - AN0429"*

Table 6715. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0150#AN0429

Analytic 0942 - AN0942

Detects execution of AutoHotKey or AutoIT interpreters or compiled scripts used for unauthorized automation, command execution, or payload delivery, correlated with anomalous process lineage, command-line arguments, or script creation events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0942 - AN0942"*

Table 6716. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0332#AN0942

Analytic 0492 - AN0492

Automated or scripted HTTP/TLS flooding from one VM or cloud instance against another service, exploiting compute-based billing or exhaustion of service infrastructure.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0492 - AN0492"*

Table 6717. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0173#AN0492

Analytic 0249 - AN0249

Correlates removable volume mounts (disk arbitration) with file I/O events on that volume, followed by same file execution shortly after insert.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0249 - AN0249"*

Table 6718. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0090#AN0249

Analytic 0924 - AN0924

AppleScript or terminal sessions launch tools (`curl`, `nc`, `ssh`) to external IPs not commonly accessed. Outbound connections are made by LaunchAgents/LaunchDaemons, often masquerading as system services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0924 - AN0924"*

Table 6719. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0325#AN0924

Analytic 0255 - AN0255

Adversary runs commands like `whoami`, `id`, `w`, or `cat /etc/passwd` from non-interactive or scripting contexts to enumerate system user details.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0255 - AN0255"*

Table 6720. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0093#AN0255

Analytic 0552 - AN0552

Alterations to plist configuration files (RulesActiveState.plist, SyncedRules.plist, UnsyncedRules.plist, MessageRules.plist) that define email hiding or filtering rules. Defender perspective: unexpected changes in these files associated with Mail.app processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0552 - AN0552"*

Table 6721. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0192#AN0552

Analytic 0525 - AN0525

Detects deletion or hiding of security-related mail rules, audit mailboxes, or calendar/log sync artifacts indicative of tampering post-intrusion.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0525 - AN0525"*

Table 6722. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0184#AN0525

Analytic 0256 - AN0256

Adversary uses `dscl`, `who`, or environment variables like `$USER` to identify accounts or sessions via Terminal or malicious LaunchAgents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0256 - AN0256"*

Table 6723. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0093#AN0256

Analytic 0652 - AN0652

Unusual use of steganographic or media processing binaries (e.g., `steghide`, `ffmpeg`, `imagemagick`) followed by outbound communication to external IPs with high data output and media MIME types.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0652 - AN0652"*

Table 6724. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0235#AN0652

Analytic 0526 - AN0526

Use of AWS STS or GCP IAM APIs to request temporary tokens or federation sessions inconsistent with normal account activity, including from unexpected principals or regions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0526 - AN0526"*

Table 6725. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0185#AN0526

Analytic 0265 - AN0265

Account attribute changes (e.g., password set, group membership, servicePrincipalName, logon hours) correlated with unusual process lineage or timing, indicating privilege escalation or persistence via valid accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0265 - AN0265"*

Table 6726. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0096#AN0265

Analytic 0625 - AN0625

Detects script or binary execution initiated via JAMF, Munki, or custom MDM agents outside of baseline, or JAMF launching new Terminal or osascript processes from remote command payloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0625 - AN0625"*

Table 6727. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0223#AN0625

Analytic 0562 - AN0562

Use of `esxcli network` commands (e.g., `esxcli network nic list`, `esxcli network ip interface ipv4 get`) via SSH or hostd to enumerate adapter and IP information.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0562 - AN0562"*

Table 6728. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0195#AN0562

Analytic 0572 - AN0572

Monitor for execution of hypervisor management commands such as `esxcli vm process list` or `vim-cmd vmsvc/getallvms` that enumerate virtual machines. Defenders observe unexpected users issuing VM listing commands outside normal administrative workflows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0572 - AN0572"*

Table 6729. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0199#AN0572

Analytic 0275 - AN0275

Unexpected write operations to BIOS/UEFI firmware regions or EFI boot partitions that do not correlate with legitimate vendor firmware updates. API calls or utilities such as fwupdate.exe or vendor flash tools executed from non-administrative or non-IT management accounts. Suspicious raw disk writes targeting System Firmware GUID partitions followed by abnormal reboot sequences.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0275 - AN0275"*

Table 6730. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0099#AN0275

Analytic 0257 - AN0257

Adversary executes CLI commands like `show users`, `show ssh`, or attempts to dump AAA user lists from routers or switches.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0257 - AN0257"*

Table 6731. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0093#AN0257

Analytic 0725 - AN0725

Detects aggregation of files from different directories into /tmp, /mnt, or user-specified directories with archiving tools like tar or gzip.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0725 - AN0725"*

Table 6732. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0261#AN0725

Analytic 0527 - AN0527

OAuth or SAML access tokens reused across multiple sessions or clients without corresponding MFA or login activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0527 - AN0527"*

Table 6733. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0185#AN0527

Analytic 0752 - AN0752

Remote login via ARD or SSH followed by screensharingd process activity or modification of TCC-protected files.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0752 - AN0752"*

Table 6734. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0269#AN0752

Analytic 0285 - AN0285

Detects web-based credential phishing by analyzing traffic to suspicious URLs that mimic login portals and POST credential content.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0285 - AN0285"*

Table 6735. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0102#AN0285

Analytic 0825 - AN0825

Detects unauthorized edits to system configuration profiles, unexpected certificate trust changes, or abnormal ARP/DNS patterns indicative of interception.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0825 - AN0825"*

Table 6736. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0296#AN0825

Analytic 0258 - AN0258

Detects creation or modification of scheduled tasks using schtasks.exe, at.exe, or COM objects followed by execution of outlier processes tied to the scheduled job.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0258 - AN0258"*

Table 6737. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0094#AN0258

Analytic 0528 - AN0528

Application access tokens used to call APIs (e.g., Google Workspace, Salesforce) without interactive logins, often with unusual scopes or elevated permissions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0528 - AN0528"*

Table 6738. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0185#AN0528

Analytic 0852 - AN0852

Application crash or repeated restart cycle triggered by malformed input or exploit file, observed via unified logs and process crash monitoring.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0852 - AN0852"*

Table 6739. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0304#AN0852

Analytic 0582 - AN0582

Detects abuse of container orchestration platforms (e.g., Kubernetes) where adversaries create CronJobs to maintain persistence or execute malicious Jobs across the cluster.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0582 - AN0582"*

Table 6740. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0206#AN0582

Analytic 0295 - AN0295

Sudden valid logins from accounts that previously had credentials dumped but had not authenticated successfully in the past; correlated with timeline of suspected hash cracking

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0295 - AN0295"*

Table 6741. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0105#AN0295

Analytic 0925 - AN0925

ESXi shell or guest VM tools initiate external connections via scripted traffic forwarding to Internet-based proxies. Detected by firewall or shell audit logs showing outbound connection spikes from hypervisor or guest VM to remote proxy nodes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0925 - AN0925"*

Table 6742. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0325#AN0925

Analytic 0259 - AN0259

Detects creation or modification of cron jobs via crontab, /etc/cron.* directories, or systemd timer units with execution by unusual users or non-standard intervals.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0259 - AN0259"*

Table 6743. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0094#AN0259

Analytic 0592 - AN0592

Domain logins using network accounts or mobile accounts via Open Directory or Active Directory plugins, especially outside business hours or on atypical endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0592 - AN0592"*

Table 6744. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0210#AN0592

Analytic 0529 - AN0529

OAuth token usage for Exchange Online or SharePoint API access without preceding login or from unauthorized clients.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0529 - AN0529"*

Table 6745. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0185#AN0529

Analytic 0952 - AN0952

Detects unauthorized modification of host binaries, modules, or services within ESXi. Correlates tampered files with subsequent unexpected service behavior or malicious module load attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0952 - AN0952"*

Table 6746. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0336#AN0952

Analytic 0266 - AN0266

Use of native tools or scripting (e.g., `usermod`, `passwd`, `groupmod`) to escalate permissions or persist access on existing users, correlated with login or process events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0266 - AN0266"*

Table 6747. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0096#AN0266

Analytic 0626 - AN0626

Detects cloud-native software deployment or management (e.g., SSM Run Command, Intune) initiating script execution on endpoints outside expected org IDs, admin groups, or maintenance windows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0626 - AN0626"*

Table 6748. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0223#AN0626

Analytic 0662 - AN0662

Adversary modifies website or application-hosted content via unauthorized file changes or script injections, often by exploiting web servers or CMS access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0662 - AN0662"*

Table 6749. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0238#AN0662

Analytic 0726 - AN0726

Detects staged data aggregated in /Users/Shared, /private/tmp with compression tools like ditto or zip, initiated via Terminal or AppleScript.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0726 - AN0726"*

Table 6750. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0261#AN0726

Analytic 0672 - AN0672

Monitor for file access to certificate directories, commands invoking OpenSSL or PKCS#12 utilities to export or modify certificates, and processes accessing sensitive key storage paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0672 - AN0672"*

Table 6751. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0240#AN0672

Analytic 0267 - AN0267

Modifications to user accounts via `dscl`, `pwpolicy`, or System Preferences CLI (`sysadminctl`) that alter user groups, enable root, or bypass MDM restrictions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0267 - AN0267"*

Table 6752. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0096#AN0267

Analytic 0627 - AN0627

Detects central router or switch config management tools (e.g., FortiManager, Cisco Prime) triggering device reboots or config pushes using abnormal accounts or IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0627 - AN0627"*

Table 6753. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0223#AN0627

Analytic 0762 - AN0762

VMware management daemons or guest processes initiating encrypted connections outside expected vCenter, update servers, or internal comms. Defender identifies hostd or vpxa initiating outbound TLS flows with uncommon destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0762 - AN0762"*

Table 6754. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0273#AN0762

Analytic 0276 - AN0276

Unauthorized firmware uploads to routers, switches, or firewalls via TFTP/FTP/SCP. Logs showing boot variable or startup image path changes redirecting to non-standard firmware images. Abnormal reboots or firmware rollback attempts following configuration modification events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0276 - AN0276"*

Table 6755. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0099#AN0276

Analytic 0268 - AN0268

Modifications to SSO/SAML user attributes (e.g., `isAdmin`, `role`, MFA bypass, App assignments) often through CLI, API, or rogue IdP apps.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0268 - AN0268"*

Table 6756. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0096#AN0268

Analytic 0286 - AN0286

Detects network share disconnection attempts using command-line tools like `net use /delete`, PowerShell `Remove-SmbMapping`, and correlation with process lineage and SMB session teardown activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0286 - AN0286"*

Table 6757. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0103#AN0286

Analytic 0682 - AN0682

Detection of persistent login hooks configured via defaults or plist modifications that result in execution of scripts or binaries at user login, breaking expected parent-child process lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0682 - AN0682"*

Table 6758. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0244#AN0682

Analytic 0628 - AN0628

Detects anomalous use of COM objects for execution, such as Office applications spawning scripting engines, enumeration of COM interfaces via registry queries, or processes loading atypical DLLs through COM activation. Correlates process creation, module loads, and registry queries to flag suspicious COM-based code execution or persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0628 - AN0628"*

Table 6759. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0224#AN0628

Analytic 0826 - AN0826

Detects unauthorized firmware or configuration changes enabling adversary-in-the-middle positioning (e.g., route injection, DNS spoofing, SSL downgrade). Behavioral analytics focus on sudden changes to routing tables or image file integrity failures.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0826 - AN0826"*

Table 6760. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0296#AN0826

Analytic 0862 - AN0862

Adversary ships a tampered application or update: an updater/installer (msiexec/setup/update.exe/vendor service) writes or replaces binaries; on first run it spawns scripts/shells or unsigned DLLs and beacons to non-approved update CDNs/hosts. Detection correlates: (1) process creation of installer/updater → (2) file metadata changes in program paths → (3) first-run children and module/signature anomalies → (4) outbound connections to unexpected hosts within a short window.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0862 - AN0862"*

Table 6761. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0309#AN0862

Analytic 0296 - AN0296

Offline cracking inferred by subsequent successful CLI or web-based authentications into routers or switches from previously dumped accounts

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0296 - AN0296"*

Table 6762. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0105#AN0296

Analytic 0629 - AN0629

Unauthorized creation or modification of DLLs loaded by LSASS, abnormal registry values under LSA extensions, and anomalous DLL load activity into the lsass.exe process context—correlated during boot or logon events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0629 - AN0629"*

Table 6763. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0225#AN0629

Analytic 0269 - AN0269

Addition of new users or changes to role permissions (e.g., ReadOnly → Admin) via API or vSphere Client, particularly from non-jumpbox IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0269 - AN0269"*

Table 6764. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0096#AN0269

Analytic 0692 - AN0692

IAAS (Cloud images/VMs): A new VM/instance is launched from a non-approved or newly-seen image (AMI/GCP Image/Azure Image). On first boot, cloud-init/user-data or embedded agents download code, spawn system utilities, or open outbound C2/mining traffic. The analytic correlates Instance/Image Creation → Instance Start → in-guest Process/Command Execution and/or anomalous network traffic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0692 - AN0692"*

Table 6765. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0248#AN0692

Analytic 0962 - AN0962

A user is socially engineered (web page, email, document) to open Run/PowerShell/CMD and paste an obfuscated one-liner. The chain is: (1) user context active in a browser/email/office app → (2) process creation of a command interpreter with suspicious arguments (base64/Invoke-Expression/web download/pipeline to shell) → (3) optional file drop in %TEMP% or %APPDATA% → (4) outbound network connection to an external domain. Events are correlated within a short window and with consistent user/session.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0962 - AN0962"*

Table 6766. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0340#AN0962

Analytic 0926 - AN0926

Changes to NAT/firewall policies enabling outbound port forwarding from internal IPs to Internet-based proxy endpoints. Log spikes in outbound flows to CDN, VPS, or anomalous ASNs with few return packets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0926 - AN0926"*

Table 6767. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0325#AN0926

Analytic 0727 - AN0727

Detects local staging behavior via snapshot creation or files written into VMFS partitions by scripts or unauthorized shell access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0727 - AN0727"*

Table 6768. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0261#AN0727

Analytic 0772 - AN0772

Behavioral chain of a user being granted elevated privileges or roles in Entra ID or Okta following suspicious login or account creation activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0772 - AN0772"*

Table 6769. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0277#AN0772

Analytic 0277 - AN0277

Detects malicious injection behavior involving memory allocation, remote thread queuing via APC (e.g., QueueUserAPC), and altered thread context within another live process to execute

unauthorized code under legitimate context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0277 - AN0277"*

Table 6770. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0100#AN0277

Analytic 0872 - AN0872

Detection of browser-based or email client-driven file creation (often from temp directories) following navigation to or execution of HTML files containing JavaScript Blob APIs or base64 Data URLs, with follow-on execution of the dropped payload. Leveraging Sysmon EventID 15 to inspect Zone.Identifier ADS for HostUrl/ReferrerUrl indicators (e.g., HostUrl=about:internet). Optional: absence of a large HTTP download record for the same URL/client in proxy logs (suggests local assembly)

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0872 - AN0872"*

Table 6771. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0313#AN0872

Analytic 0782 - AN0782

Monitors for compression tool usage (e.g., 7zip, WinRAR, MakeCab) that follows or precedes file modification, suspicious file types (e.g., .exe, .dll) being compressed, or dropped from self-extracting archives followed by immediate execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0782 - AN0782"*

Table 6772. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0281#AN0782

Analytic 0827 - AN0827

Processes attempting raw disk access to overwrite sensitive structures such as the MBR or partition table using \\.\PhysicalDrive notation. Detection relies on correlating process creation, privilege escalation, and raw sector writes in Sysmon and Security logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0827 - AN0827"*

Table 6773. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0297#AN0827

Analytic 0287 - AN0287

Detects modification of LSASS and authentication DLLs, suspicious registry changes to password filter packages, and abnormal process access to lsass.exe. Correlates registry modifications, DLL loads, and process handle access events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0287 - AN0287"*

Table 6774. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0104#AN0287

Analytic 0278 - AN0278

Detects execution of Lua interpreters or scripts (.lua), especially when correlated with suspicious parent processes or file drop events, indicating malicious use of embedded scripting.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0278 - AN0278"*

Table 6775. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0101#AN0278

Analytic 0728 - AN0728

Monitor DNS query results where subsequent connections use derived or unusual port numbers not explicitly resolved, especially when tied to suspicious processes. Correlate Sysmon DNS logs (Event ID 22) with process creation and socket activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0728 - AN0728"*

Table 6776. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0262#AN0728

Analytic 0972 - AN0972

VM or cloud instance generating anomalously high network egress targeting same destination IP or service, especially using stateless protocols.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0972 - AN0972"*

Table 6777. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0343#AN0972

Analytic 0729 - AN0729

Inspect resolver and audit logs for processes initiating outbound connections to ports calculated from DNS response IPs. Abnormal ephemeral port usage shortly after DNS queries can indicate DNS calculation behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0729 - AN0729"*

Table 6778. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0262#AN0729

Analytic 0927 - AN0927

A process/script constructs or references a custom/alphabet translation table (e.g., 64/85/32+ arbitrary chars, XOR/base-N loops) or emits long high-entropy strings that do NOT validate as standard Base64/Hex → shortly after, the same process (or its child) generates outbound traffic with asymmetric bytes_out:bytes_in, fixed-size beacons, or protocol/header mismatches (e.g., Content-Type says JSON but body fails JSON parse / contains non-standard alphabet).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0927 - AN0927"*

Table 6779. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0326#AN0927

Analytic 0297 - AN0297

Detects PE injection through a behavioral sequence where one process opens (OpenProcess) a handle to another, allocates remote memory (VirtualAllocEx), writes a PE header (MZ) or shellcode (WriteProcessMemory), then initiates a new thread (CreateRemoteThread or NtCreateThreadEx) in that process—executing injected code in memory without touching disk. Optional: injects a trampoline or shellcode that unpacks/reflectively maps the payload.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0297 - AN0297"*

Table 6780. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0106#AN0297

Analytic 0792 - AN0792

Monitor for anomalous email activity originating from Windows-hosted applications (e.g., Outlook) where the sending account name or display name does not match the underlying SMTP address. Detect abnormal volume of outbound messages containing sensitive keywords (e.g., 'payment', 'wire transfer') or anomalous login locations for accounts associated with email sending activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0792 - AN0792"*

Table 6781. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0286#AN0792

Analytic 0279 - AN0279

Detects invocation of lua or luajit interpreters by users or services outside of expected packages, chained with script drop or memory artifacts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0279 - AN0279"*

Table 6782. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0101#AN0279

Analytic 0828 - AN0828

Execution of utilities (dd, hdparm, sgdisk) or custom binaries attempting to overwrite disk boot structures (/dev/sda MBR sector or partition tables). Detection correlates shell execution with syscalls writing to sector 0 or disk metadata blocks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0828 - AN0828"*

Table 6783. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0297#AN0828

Analytic 0288 - AN0288

Detects modification of PAM configuration files, unauthorized new PAM modules, and suspicious process execution accessing PAM-related binaries. Correlates file modification events in /etc/pam.d/ with process execution of unauthorized binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0288 - AN0288"*

Table 6784. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0104#AN0288

Analytic 0882 - AN0882

Processes attempting raw disk access via \\.\PhysicalDrive paths, abnormal file I/O to MBR/boot sectors, or loading of third-party drivers (e.g., RawDisk) that enable disk overwrite. Correlate process creation, privilege usage, and disk modification events within a short time window.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0882 - AN0882"*

Table 6785. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0316#AN0882

Analytic 0928 - AN0928

Shell scripts or binaries implement custom mapping tables (tr/sed/awk/golang/rust/python encode loops), or emit long high-entropy tokens that fail Base64/Hex validation → correlated with egress showing asymmetric flow, protocol-mismatch payloads, or DNS/HTTP bodies containing low-diversity-but-long custom alphabets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0928 - AN0928"*

Table 6786. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0326#AN0928

Analytic 0892 - AN0892

Changes to security configurations such as disabling MFA requirements, reducing session token lifetimes, or turning off risk-based policies. Correlate admin logins with sudden policy downgrades.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0892 - AN0892"*

Table 6787. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0892

Analytic 0982 - AN0982

Use of tools like xwd or import to generate screenshots, especially under non-GUI parent processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0982 - AN0982"*

Table 6788. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0346#AN0982

Analytic 0829 - AN0829

Abnormal invocation of diskutil or asr that modifies partition tables or initializes raw devices. Monitor for IOKit system calls targeting disk headers or EFI boot sectors, correlated with elevated privileges.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0829 - AN0829"*

Table 6789. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0297#AN0829

Analytic 0298 - AN0298

Correlation of inbound emails with embedded links followed by user-driven browser navigation to suspicious or obfuscated domains. Detection chain includes malicious URL in email → user click recorded in Office logs → browser process spawning unusual child processes (e.g., PowerShell, cmd) or download activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0298 - AN0298"*

Table 6790. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0107#AN0298

Analytic 0289 - AN0289

Detects unauthorized additions or changes to /Library/Security/SecurityAgentPlugins and suspicious process activity attempting to hook authentication APIs. Correlates file modifications with abnormal plugin loads in authentication flows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0289 - AN0289"*

Table 6791. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0104#AN0289

Analytic 0992 - AN0992

Detect suspicious file creations and process executions triggered by browser activity (e.g., injected

payloads written to %AppData% or Temp directories, then executed). Correlate network anomalies with subsequent local process creation or script execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0992 - AN0992"*

Table 6792. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0349#AN0992

Analytic 0929 - AN0929

EndpointSecurity/Unified Logs show processes generating custom alphabets or long high-entropy, non-standard tokens → network logs (PF/Zeek/EDR) show asymmetric beacons, protocol mismatches, or periodic fixed-size posts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0929 - AN0929"*

Table 6793. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0326#AN0929

Analytic 0299 - AN0299

Detection of spearphishing links through mail logs and browser activity. Behavior includes email with suspicious URLs → user click recorded in mail/web proxy logs → shell or interpreter launched from browser process.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0299 - AN0299"*

Table 6794. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0107#AN0299

Analytic 0333 - AN0333

Detects manipulation of PNG, JPG, or GIF files by user-initiated scripts followed by script execution or exfiltration behavior, especially from `osascript`, `python`, or `bash`, in combination with LaunchAgent persistence or curl activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0333 - AN0333"*

Table 6795. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0119#AN0333

Analytic 0433 - AN0433

Interactive or remote shell/API invocation of esxcli system clock get or querying time parameters via hostd/vpxa shortly followed by time/ntp configuration checks or scheduled task creation, executed by non-standard accounts or outside maintenance windows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0433 - AN0433"*

Table 6796. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0151#AN0433

Analytic 0343 - AN0343

Detects mounted external devices (via /media or /mnt) followed by large file read or copy operations by shell scripts, unauthorized users, or staging tools (e.g., tar, rsync).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0343 - AN0343"*

Table 6797. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0123#AN0343

Analytic 0334 - AN0334

Correlated user account modification (reset, disable, deletion) events with anomalous process lineage (e.g., PowerShell or net.exe from an interactive session), especially outside of IT admin change windows or by non-admin users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0334 - AN0334"*

Table 6798. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0120#AN0334

Analytic 0335 - AN0335

Password changes or account deletions via 'passwd', 'userdel', or 'chage' preceded by interactive shell or remote command execution from non-privileged accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0335 - AN0335"*

Table 6799. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0120#AN0335

Analytic 0353 - AN0353

Direct modification of /etc/ssh/keys-<user>/authorized_keys or enabling SSH in sshd_config to support public key auth.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0353 - AN0353"*

Table 6800. Table References

https://attack.mitre.org/detectionstrategies/DET0126#AN0353

Analytic 0533 - AN0533

Use of pbpaste, AppleScript, or third-party automation frameworks (e.g., Automator) to collect clipboard or file content in bursts. Observable via unified logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0533 - AN0533"*

Table 6801. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0186#AN0533

Analytic 0363 - AN0363

Adversary enumeration of domain accounts using net.exe, PowerShell, WMI, or LDAP queries from non-domain controllers or non-admin endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0363 - AN0363"*

Table 6802. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0129#AN0363

Analytic 0633 - AN0633

Processes initiating outbound connections on uncommon ports or using protocols inconsistent with the assigned port. Correlating process creation with subsequent network connections reveals anomalies such as svchost.exe or Office applications using high, atypical ports.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0633 - AN0633"*

Table 6803. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0227#AN0633

Analytic 0336 - AN0336

Execution of dscl or sysadminctl commands to disable, delete, or modify users combined with anomalous process ancestry or terminal session launch.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0336 - AN0336"*

Table 6804. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0120#AN0336

Analytic 0337 - AN0337

Invocation of esxcli 'system account remove' from vCLI, SSH, or vSphere API with anomalous user access or outside maintenance windows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0337 - AN0337"*

Table 6805. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0120#AN0337

Analytic 0733 - AN0733

Detects JavaScript execution through WSH (wscript.exe, cscript.exe) or HTA (mshta.exe), particularly when spawned from Office macros, web browsers, or abnormal user paths. Correlates script execution with outbound network activity or system modification.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0733 - AN0733"*

Table 6806. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0264#AN0733

Analytic 0373 - AN0373

File lock acquired via open() + flock() or lockf() on predictable path (e.g., /tmp/.lock123) followed by conditional early exit or divergent process behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0373 - AN0373"*

Table 6807. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0132#AN0373

Analytic 0833 - AN0833

Detects invocation of macOS-native archiving utilities (zip, ditto, hdiutil) or openssl used for encryption. Correlates execution with archive or encrypted file creation (.zip, .dmg, .tar.gz) in user or temporary directories. Identifies anomalous use of archiving commands by Office applications or daemons.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0833 - AN0833"*

Table 6808. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0298#AN0833

Analytic 0338 - AN0338

O365 UnifiedAuditLog entries for Remove-Mailbox or Set-Mailbox with account disable or delete actions correlated with suspicious login locations or MFA bypass.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0338 - AN0338"*

Table 6809. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0120#AN0338

Analytic 0383 - AN0383

Detection of unauthorized modification of Active Directory SID-History attributes to escalate privileges. This chain involves: (1) privileged operations or API calls to DsAddSidHistory or related AD modification functions, (2) observed attribute changes in SID-History (Event ID 5136), (3) new logon sessions where the token includes unexpected or privileged SID-History values, and (4) follow-on resource access using elevated privileges derived from SID-History injection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0383 - AN0383"*

Table 6810. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0136#AN0383

Analytic 0393 - AN0393

Detects deletion of suspicious files (e.g., payloads, temp exes, scripts) via `rm`, `unlink`, or secure

deletion tools like `shred`, especially when performed by unexpected users or shortly after execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0393 - AN0393"*

Table 6811. Table References

Links

Use of command-line like `ip ssh pubkey-chain` to bind SSH keys to privileged accounts on routers or switches.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0354 - AN0354"*

Table 6818. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0126#AN0354

Analytic 0345 - AN0345

Process invokes a standard encoder (e.g., PowerShell -enc, certutil -encode, base64 via .NET/Invoke-Expression) or emits long Base64/hex literals → shortly followed by outbound network egress with high bytes_out:bytes_in ratio or HTTP headers/payloads containing Base64/MIME blocks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0345 - AN0345"*

Table 6819. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0124#AN0345

Analytic 0543 - AN0543

Detects registry and Group Policy modifications that disable or weaken MFA, suspicious PowerShell usage modifying MFA-related attributes, and anomalous login sessions succeeding without expected MFA challenge.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0543 - AN0543"*

Table 6820. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0190#AN0543

Analytic 0435 - AN0435

Detection focuses on adversaries placing or modifying malicious dylibs in locations searched by legitimate applications. From the defender's perspective, observable patterns include unexpected creation or modification of dylib files in application bundle paths, unusual module loads by processes compared to historical baselines, and execution of applications loading dylibs from suspicious directories (e.g., /tmp, user-controlled paths). Correlation across file system changes, process execution, and module loads provides high-fidelity detection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0435 - AN0435"*

Table 6821. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0152#AN0435

Analytic 0453 - AN0453

Detect anomalous OAuth or SSO logins that repeatedly generate MFA challenges, particularly where MFA approvals are denied or timed out by the user.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0453 - AN0453"*

Table 6822. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0160#AN0453

Analytic 0364 - AN0364

Domain account enumeration using ldapsearch, samba tools (e.g., 'wbinfo -u'), or winbindd lookups.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0364 - AN0364"*

Table 6823. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0129#AN0364

Analytic 0346 - AN0346

Shell/utility (base64, xxd -p, od, openssl enc -base64, python/perl base64 libraries) encodes data → subsequent outbound connections (curl/wget/bash TCP, socat, python requests) with high asymmetry or Base64/MIME blobs in HTTP/DNS payloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0346 - AN0346"*

Table 6824. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0124#AN0346

Analytic 0436 - AN0436

Unusual processes (e.g., powershell.exe, wscript.exe, mshta.exe) posting data to webhook endpoints (Discord, Slack, webhook.site) using HTTP POST/PUT requests. Defender perspective: suspicious process lineage followed by outbound HTTPS traffic to webhook domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0436 - AN0436"*

Table 6825. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0153#AN0436

Analytic 0643 - AN0643

Detects execution of binaries signed with unusual or recently issued certificates, correlation of process execution with abnormal publisher metadata, and mismatched certificate chains. Monitors for revoked or unknown code signing certificates used in high-privilege contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0643 - AN0643"*

Table 6826. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0230#AN0643

Analytic 0463 - AN0463

Process creates a raw/packet socket and attaches a (e)BPF filter (setsockopt SO_ATTACH_FILTER/ATTACH_BPF or bpf(BPF_PROG_LOAD)). Immediately after a matching inbound packet, the same process binds/connects outward to a remote host (reverse shell or beacon).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0463 - AN0463"*

Table 6827. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0264#AN0734

Analytic 0834 - AN0834

Sequential behavioral chain of privilege escalation through permission modification: (1) Process creation of permission-modifying utilities (icacls, takeown, attrib, cacls), (2) Correlation with unusual user context or timing, (3) DACL modification events targeting sensitive files/directories, (4) Subsequent file access or modification attempts indicating successful privilege bypass

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0834 - AN0834"*

Table 6835. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0299#AN0834

Analytic 0348 - AN0348

ESXi shell (BusyBox) or VMware utilities (openssl, python if present) used to Base64/hex encode data from datastore or config files → followed by abnormal egress from the host (NSX/flow logs) with asymmetric bytes_out or HTTPS posts to non-management endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0348 - AN0348"*

Table 6836. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0124#AN0348

Analytic 0384 - AN0384

Unusual direct disk access attempts (e.g., use of \\.\PhysicalDrive notation), abnormal writes to MBR/boot sectors, and installation of kernel drivers that grant raw disk access. Correlate anomalous process creation with disk modification attempts and driver loads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0384 - AN0384"*

Table 6837. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0137#AN0384

Analytic 0843 - AN0843

A source performs a short closed-port sequence; the host then modifies iptables/nftables/ufw rules or starts a daemon binding a new socket, followed by a successful connection from the same source.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0843 - AN0843"*

Table 6838. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0302#AN0843

Analytic 0483 - AN0483

Forged cookies in IaaS environments may appear as authentication attempts that bypass MFA, leveraging AssumeRole or session APIs with cookies that were never legitimately issued. Defenders should correlate cloud logs for cookie-based sessions without prior valid authentication, often followed by resource access from unfamiliar IP addresses.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0483 - AN0483"*

Table 6839. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0171#AN0483

Analytic 0438 - AN0438

Unexpected apps or scripts (osascript, curl, Automator workflows) exfiltrating data via webhooks. Defender perspective: correlation of clipboard/file read operations followed by HTTPS POST traffic to webhook services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0438 - AN0438"*

Table 6840. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0153#AN0438

Analytic 0934 - AN0934

Shell utilities or scripts deleting `/etc/systemd/system/rescue.target`, `/etc/fstab` backups, or `/boot/efi` partitions; chattr used to block snapshot auto-recovery

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0934 - AN0934"*

Table 6841. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0329#AN0934

Analytic 0394 - AN0394

Detects removal of adversary artifacts via `rm`, `unlink`, or secure tools, with focus on shell sessions, temp files, and modified LaunchAgents or system directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0394 - AN0394"*

Table 6842. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0140#AN0394

Analytic 0493 - AN0493

Detects adversary exploitation of authentication mechanisms or credential validation processes. Defender perspective includes forged Kerberos tickets (e.g., MS14-068), abnormal LSASS memory access, replayed authentication attempts, and unexpected crashes of authentication services. Multi-event correlation ties exploitation attempts to abnormal process creation, service instability, and suspicious authentication events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0493 - AN0493"*

Table 6843. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0174#AN0493

Analytic 0439 - AN0439

VMware services or management daemons generating HTTP POST requests to webhook endpoints, chained with unusual datastore or log access. Defender perspective: exfiltration from VM logs or disk images over webhook URLs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0439 - AN0439"*

Table 6844. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0153#AN0439

Analytic 0349 - AN0349

Unusual modification or creation of loginwindow-related plist files in '~/Library/Preferences/ByHost' correlated with unauthorized application paths and execution upon login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0349 - AN0349"*

Table 6845. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0125#AN0349

Analytic 0943 - AN0943

Detects creation of scheduled tasks via `at.exe` or WMI `Win32_ScheduledJob` class, followed by execution of anomalous processes by svchost.exe or taskeng.exe.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0943 - AN0943"*

Table 6846. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0188#AN0536

Analytic 0563 - AN0563

CLI-based execution of interface and routing discovery commands (e.g., `show ip interface`, `show arp`, `show route`) over Telnet, SSH, or console.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0563 - AN0563"*

Table 6853. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0195#AN0563

Analytic 0653 - AN0653

Abnormal usage of Preview, ImageMagick, or binary editors to alter images/documents, followed by exfiltration or outbound connections with mismatched file MIME types or payload structure.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0653 - AN0653"*

Table 6854. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0235#AN0653

Analytic 0365 - AN0365

Domain group and user enumeration via dscl or dscacheutil, or queries to directory services from non-admin endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0365 - AN0365"*

Table 6855. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0129#AN0365

Analytic 0537 - AN0537

Abnormal use of `lsblk`, `fdisk -l`, `lshw -class disk`, or `parted` by non-admin users or within non-interactive shells suggests suspicious disk enumeration activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0537 - AN0537"*

Table 6856. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0188#AN0537

Analytic 0735 - AN0735

Detects Node.js or JavaScript interpreter execution from web shells, cron jobs, or local users. Correlates execution with reverse shell behavior, file modifications, or abnormal outbound connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0735 - AN0735"*

Table 6857. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0264#AN0735

Analytic 0573 - AN0573

Detects attempts to enumerate VMs via hypervisor tools like `virsh`, `VBoxManage`, or `qemu-img`. Defender correlates suspicious command invocations with parent process lineage and unexpected users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0573 - AN0573"*

Table 6858. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0199#AN0573

Analytic 0357 - AN0357

Adversary creates disguised launch daemons or apps with misleading names and bundle metadata (e.g., Info.plist values inconsistent with binary path or icon). Launch is correlated with user logon or persistence setup.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0357 - AN0357"*

Table 6859. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0127#AN0357

Analytic 0753 - AN0753

Use of cloud-based bastion or VM console session followed by commands that initiate outbound SSH or RDP sessions from the cloud instance to other environments.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0753 - AN0753"*

Table 6860. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0269#AN0753

Analytic 0375 - AN0375

Detection of the creation of VSCode or JetBrains CLI tunneling profiles followed by persistent remote access via IDE-integrated tunnels, potentially authenticated via GitHub or JetBrains accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0375 - AN0375"*

Table 6861. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0133#AN0375

Analytic 0358 - AN0358

Adversary uses renamed container images, injects files into containers with misleading names or metadata (e.g., renamed system binaries), and executes them during startup or scheduled jobs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0358 - AN0358"*

Table 6862. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0127#AN0358

Analytic 0538 - AN0538

Disk enumeration via `diskutil list` or `system_profiler SPStorageDataType` run outside of user login or not associated with system inventory tools

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0538 - AN0538"*

Table 6863. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0188#AN0538

Analytic 0583 - AN0583

Registry modification of the LSA Authentication Packages key followed by LSASS loading a non-standard or unsigned DLL. This includes unusual write access to `HKLM\SYSTEM\CurrentControlSet\Control\Lsa`, especially during non-installation timeframes. Correlated with `lsass.exe` loading DLLs not present in baseline or lacking valid signatures.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0583 - AN0583"*

Table 6864. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0207#AN0583

Analytic 0385 - AN0385

Processes invoking destructive commands (dd, shred, wipe) with raw device targets (e.g., /dev/sda, /dev/nvme0n1). Detect direct writes to disk partitions and abnormal superblock or bootloader modifications. Correlate shell execution with subsequent block device I/O.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0385 - AN0385"*

Table 6865. Table References

Links

Analytic 0835 - AN0835

Behavioral sequence of unauthorized privilege escalation via permission modification: (1) chmod/chown/setfacl process execution with suspicious parameters, (2) Targeting of critical system files or unusual permission values, (3) Correlation with non-privileged user context or unusual timing patterns, (4) Follow-on file access indicating successful permission bypass

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0835 - AN0835"*

Table 6866. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0299#AN0835

Analytic 0853 - AN0853

Cloud workload exploitation leads to repeated container, service, or VM termination/restart, typically associated with CVE-based crash triggers or fuzzed payloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0853 - AN0853"*

Table 6867. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0304#AN0853

Analytic 0395 - AN0395

Detects manual or scripted removal of logs, artifacts, or malware droppings via `rm` or PowerCLI in ESXi shell. Focus on deletions from /tmp/, /var/core/, or /scratch.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0395 - AN0395"*

Table 6868. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0140#AN0395

Analytic 0539 - AN0539

Use of `esxcli storage` or `vim-cmd vmsvc/getallvms` by unusual sessions or through interactive shells unrelated to administrative maintenance tasks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0539 - AN0539"*

Table 6869. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0188#AN0539

Analytic 0953 - AN0953

Defenders can detect suspicious reversion of cloud compute instances by monitoring for unusual snapshot restores, rollback actions, or ephemeral storage resets that occur outside expected administrative workflows. From a defender's perspective, relevant detection chains include: a snapshot restore triggered by a new or rarely used account, a sequence of snapshot creation immediately followed by a restore and instance start, or rollbacks performed from anomalous geographic or network locations. These patterns may indicate attempts to remove forensic evidence or re-establish a clean execution state for persistence.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0953 - AN0953"*

Table 6870. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0337#AN0953

Analytic 0935 - AN0935

ESXi shell or vim-cmd execution that deletes all VM snapshots using vmsvc/snapshot.removeall or rm on snapshot paths

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0935 - AN0935"*

Table 6871. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0329#AN0935

Analytic 0359 - AN0359

Adversary places scripts or binaries with misleading names in /etc/rc.local.d or /var/spool/cron, or registers services with legitimate-sounding names not present in default ESXi builds.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0359 - AN0359"*

Table 6872. Table References

https://attack.mitre.org/detectionstrategies/DET0249#AN0693

Analytic 0369 - AN0369

Detects non-native file transfer via curl, Python scripts, or AppleScript using uncommon protocols like FTP, SMTP, or DNS exfiltration through mDNSResponder abuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0369 - AN0369"*

Table 6894. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0131#AN0369

Analytic 0377 - AN0377

Detection of JetBrains or VSCode tunnel profile creation followed by unusual persistent SSH or IDE-based tunnel communications to devtunnel APIs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0377 - AN0377"*

Table 6895. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0133#AN0377

Analytic 0773 - AN0773

Detection of new admin or role assignment actions within Microsoft 365/O365 environments to elevate access for persistence or lateral movement.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0773 - AN0773"*

Table 6896. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0277#AN0773

Analytic 0737 - AN0737

Detects mailbox manipulation or deletion via PowerShell (e.g., Remove-MailboxExportRequest), file deletion from Outlook data stores (Unistore.db), or tampering with quarantined mail logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0737 - AN0737"*

Table 6897. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0266#AN0737

Analytic 0837 - AN0837

ESXi hypervisor permission modification behavioral chain: (1) SSH access to ESXi host, (2) chmod/chown execution on VMFS datastore files or system configuration, (3) Modification of VM configuration files (.vmx) or virtual disk permissions, (4) Hostd service log correlation, (5) vCenter permission change events if centrally managed

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0837 - AN0837"*

Table 6898. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0299#AN0837

Analytic 0378 - AN0378

Detects unauthorized access to Windows Credential Manager through anomalous process execution (vaultcmd.exe, rundll32.exe keymgr.dll), suspicious API calls (CredEnumerateA), or direct file access to Credential Locker files. Correlates process creation with subsequent file reads of .vcrd/.vpol files under user Credential Locker directories.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0378 - AN0378"*

Table 6899. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0134#AN0378

Analytic 0873 - AN0873

Detection of browser-based downloads from HTML sources that trigger file creation in temp or user directories followed by execution of new files within short timeframes and suspicious parent-child lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0873 - AN0873"*

Table 6900. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0313#AN0873

Analytic 0783 - AN0783

Detects sequential command-line compression utilities (e.g., gzip, tar, zip, 7z) followed by execution of unpacked files, especially in temp directories or under non-standard locations like /dev/shm or /tmp with ELF binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0783 - AN0783"*

Table 6901. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0281#AN0783

Analytic 0387 - AN0387

Execution of destructive CLI commands such as 'erase startup-config', 'erase flash:' or 'format disk' on routers/switches. Detect privilege level escalation preceding destructive commands.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0387 - AN0387"*

Table 6902. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0137#AN0387

Analytic 0738 - AN0738

Detects the use of mail utilities like `mail` or `mailx` to delete mailbox content, or file-level deletion of inbox files from `/var/spool/mail/` or `/var/mail/` following suspicious sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0738 - AN0738"*

Table 6903. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0266#AN0738

Analytic 0397 - AN0397

Script-based execution of sleep loops or time delay commands (e.g., sleep, ping delay, while-loops) followed by file creation or network connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0397 - AN0397"*

Table 6904. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0141#AN0397

Analytic 0973 - AN0973

Detects abuse of fileless storage mechanisms such as Registry keys, WMI classes, and Event Logs used to stage payloads, scripts, or encoded content outside traditional files.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0973 - AN0973"*

Table 6905. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0344#AN0973

Analytic 0793 - AN0793

Monitor mail server logs (Postfix, Sendmail, Exim) for anomalous From headers mismatching authenticated SMTP identities. Detect abnormal relay attempts, spoofed envelope-from values, or large-scale outbound campaigns targeting internal users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0793 - AN0793"*

Table 6906. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0286#AN0793

Analytic 0379 - AN0379

Detects unauthorized use of SMTP/IMAP/POP3 by suspicious binaries (e.g., PowerShell, rundll32) to exfiltrate data or beacon via email, often bypassing proxy or content filters.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0379 - AN0379"*

Table 6907. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0135#AN0379

Analytic 0739 - AN0739

Detects removal of Apple Mail artifacts via AppleScript or direct deletion of mailbox content in ~/Library/Mail/, especially when preceded by Remote Login or C2-related API access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0739 - AN0739"*

Table 6908. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0266#AN0739

Analytic 0937 - AN0937

Cloud API calls disabling snapshot scheduling, backup policies, versioning, followed by DeleteSnapshot/DeleteVolume operations

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0937 - AN0937"*

Table 6909. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0329#AN0937

Analytic 0838 - AN0838

Detect anomalous chains of memory allocation and execution inside the same process (e.g., VirtualAlloc → memcpy → VirtualProtect → CreateThread). Unlike process injection, reflective code loading does not perform cross-process memory writes — the suspicious activity occurs entirely within the process's own PID context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0838 - AN0838"*

Table 6910. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0300#AN0838

Analytic 0883 - AN0883

Execution of destructive utilities (dd, shred, wipe) targeting block devices, or processes invoking syscalls to directly overwrite /dev/sd* or /dev/nvme* partitions. Correlate abnormal file write attempts with shell process execution and block device access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0883 - AN0883"*

Table 6911. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0316#AN0883

Analytic 0388 - AN0388

Execution of InstallUtil.exe from .NET framework directories with arguments specifying non-standard or attacker-supplied assemblies, especially when followed by suspicious child process creation or script execution. Detection also includes correlation of newly created binaries prior to InstallUtil invocation and anomalous command-line usage compared to historical baselines.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0388 - AN0388"*

Table 6912. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0138#AN0388

Analytic 0938 - AN0938

Correlation of package install event with execution of postinstall scripts containing unknown binaries or abnormal CLI usage. Look for `/usr/sbin/installer` execution followed by child processes originating from postinstall script.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0938 - AN0938"*

Table 6913. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0330#AN0938

Analytic 0983 - AN0983

Detects processes or binaries executed from trusted directories (e.g., System32) or using trusted names (e.g., svchost.exe) where the metadata, hash, or parent process does not align with legitimate activity patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0983 - AN0983"*

Table 6914. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0347#AN0983

Analytic 0389 - AN0389

Detects credential harvesting via userland API hooking (e.g., SetWindowsHookEx, IAT, or inline patching) by correlating memory modifications with hook installation functions and suspicious module loads in credential-sensitive processes like lsass.exe, explorer.exe, or winlogon.exe.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0389 - AN0389"*

Table 6915. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0139#AN0389

Analytic 0839 - AN0839

Monitor for in-process mmap + mprotect + execve/execveat activity where memory permissions are changed from writable to executable inside the same process without a corresponding ELF on disk.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0839 - AN0839"*

Table 6916. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0300#AN0839

Analytic 0893 - AN0893

Execution of commands disabling AAA, logging, or security features on routers/switches. Detect privilege escalation followed by config changes that disable defense mechanisms.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0893 - AN0893"*

Table 6917. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0893

Analytic 0398 - AN0398

Use of `usleep`, `nanosleep`, or `NSTimer` calls in executables or binaries with no GUI interaction, especially followed by disk/network activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0398 - AN0398"*

Table 6918. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0141#AN0398

Analytic 0939 - AN0939

Detection of maintainer scripts (e.g., postinst, preinst) being modified or executed during dpkg or rpm operations. Watch for script content that spawns additional processes or writes outside package scope.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0939 - AN0939"*

Table 6919. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0330#AN0939

Analytic 0399 - AN0399

Detects unauthorized or anomalous use of command-line interfaces (CLI) on network devices. Focuses on remote access sessions (e.g., SSH/Telnet), privilege escalation within CLI sessions, execution of high-risk commands (e.g., config replace, terminal monitor, no logging), and configuration changes outside of approved windows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0399 - AN0399"*

Table 6920. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0142#AN0399

Analytic 0993 - AN0993

Detect curl/wget commands saving executable/script payloads to /tmp or /var/tmp followed by execution. Monitor packet captures or IDS/IPS alerts for injected responses or mismatched content types.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0993 - AN0993"*

Table 6921. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0349#AN0993

Analytic 0444 - AN0444

Detects Kerberoasting attempts by monitoring for anomalous Kerberos TGS requests (Event ID 4769) with RC4 encryption (etype 0x17), accounts requesting an unusual number of service tickets in a short period, or service accounts targeted outside normal usage baselines. Also correlates suspicious process activity (e.g., Mimikatz invoking LSASS access) with Kerberos ticket anomalies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0444 - AN0444"*

Table 6922. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0157#AN0444

Analytic 0544 - AN0544

Detects conditional access policy changes, exclusion of accounts from MFA enforcement, or registration of new MFA factors by non-admin or anomalous users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0544 - AN0544"*

Table 6923. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0190#AN0544

Analytic 0454 - AN0454

Detect user account logon attempts that trigger multiple MFA challenges through enterprise identity integrations, especially if MFA push requests are generated without successful interactive

login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0454 - AN0454"*

Table 6924. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0160#AN0454

Analytic 0445 - AN0445

Detection of msiexec.exe execution where command-line arguments reference remote MSI packages, UNC paths, HTTP/HTTPS URLs, or DLLs, correlated with subsequent module loads and/or network connections to previously unseen destinations. The behavioral chain links process creation of msiexec.exe with suspicious parameters, network activity to retrieve payloads, and module loading indicative of malicious installation or DLL execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0445 - AN0445"*

Table 6925. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0158#AN0445

Analytic 0644 - AN0644

Monitors Gatekeeper, spctl, and unified log entries for binaries executed with unexpected or untrusted signatures. Correlates file metadata changes with process launches where signature validation is skipped, altered, or fails but the process still executes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0644 - AN0644"*

Table 6926. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0230#AN0644

Analytic 0446 - AN0446

Detection of USB-based remote access hardware (e.g., TinyPilot, PiKVM) attached to the host via drive or peripheral enumeration, triggering vendor identifiers or unusual EDID announcements.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0446 - AN0446"*

Table 6927. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0159#AN0446

Analytic 0464 - AN0464

Process opens /dev/bpf* (libpcap) or loads NetworkExtension filter, then after a crafted inbound packet the same process initiates an outbound connection to the trigger origin.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0464 - AN0464"*

Table 6928. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0162#AN0464

Analytic 0447 - AN0447

Insertion of USB-based hardware proxies (e.g., PiKVM) which register under predictable names (e.g., tinypilot) or mount under known paths (e.g., /opt/tinypilot-privileged).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0447 - AN0447"*

Table 6929. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0159#AN0447

Analytic 0744 - AN0744

Sudden spikes in cloud VM CPU usage with outbound traffic to mining pools and unauthorized instance creation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0744 - AN0744"*

Table 6930. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0267#AN0744

Analytic 0474 - AN0474

Firmware flash utility invoked with elevated privileges followed by raw access to firmware device path or changes to boot configuration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0474 - AN0474"*

Table 6931. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0167#AN0474

Analytic 0484 - AN0484

Forged web cookies on Windows endpoints can be detected by monitoring unusual modifications of browser cookie stores (e.g., Chrome SQLite DB, Edge cache) by processes outside of browsers, followed by authentication events to SaaS or IaaS services. Defenders may observe processes writing directly to cookie storage paths or injecting tokens into browser sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0484 - AN0484"*

Table 6932. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0171#AN0484

Analytic 0844 - AN0844

A source performs a closed-port sequence; the endpoint enables a PF/socketfilterfw rule or a background process binds a port; then a successful connection completes from the same source.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0844 - AN0844"*

Table 6933. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0302#AN0844

Analytic 0448 - AN0448

Attachment of hardware-backed USB KVM devices (e.g., TinyPilot) that enumerate new HID or serial communication interfaces with identifiable metadata.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0448 - AN0448"*

Table 6934. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0159#AN0448

Analytic 0494 - AN0494

Detects exploitation of authentication daemons or PAM modules. Defender perspective includes failed or anomalous PAM authentications, abnormal segfaults in authentication services, and exploitation attempts followed by successful unauthorized logins. Correlation identifies memory corruption, replay attempts, and privilege escalation tied to credential services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0494 - AN0494"*

Table 6935. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0174#AN0494

Analytic 0944 - AN0944

Detects usage of `at` command to schedule jobs, followed by job execution and modification of job files under /var/spool/cron/atjobs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0944 - AN0944"*

Table 6936. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0333#AN0944

Analytic 0449 - AN0449

Monitor for excessive or anomalous MFA push notifications or token requests, especially when login attempts originate from unusual IPs or geolocations and do not correspond to legitimate user-initiated sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0449 - AN0449"*

Table 6937. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0160#AN0449

Analytic 0545 - AN0545

Detects API calls to cloud secrets/MFA configurations where MFA enforcement policies are disabled or bypassed.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0545 - AN0545"*

Table 6938. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0190#AN0545

Analytic 0554 - AN0554

Suspicious rule creation within Outlook or Exchange clients, including auto-move or delete conditions tied to incident or security alert keywords. Defender perspective: correlation between missing inbound emails and newly added mailbox rules.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0554 - AN0554"*

Table 6939. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0192#AN0554

Analytic 0455 - AN0455

Cause→effect chain: (1) a user or service spawns a shell/PowerShell that queries local/domain password policy via commands/cmdlets (e.g., `net accounts`, `Get-ADDefaultDomainPasswordPolicy`, `secedit /export`); (2) optional directory/LDAP reads from DCs; (3) same principal performs adjacent Discovery or credential-related actions within a short window. Correlate sysmon process creation with PowerShell ScriptBlock and Security logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0455 - AN0455"*

Table 6940. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0161#AN0455

Analytic 0465 - AN0465

Defenders may observe unauthorized or anomalous changes to NAT configurations, including the addition of new translation rules or modifications to existing ones. Suspicious behaviors include sudden introduction of NAT mappings bridging segmented networks, new port address translation rules that obscure true source IPs, or traffic flows inconsistent with expected network design. Multi-event correlation includes detecting configuration changes on routers/firewalls, followed by traffic traversing unexpected internal/external address pairs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0465 - AN0465"*

Table 6941. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0163#AN0465

Analytic 0654 - AN0654

Suspicious modification of file artifacts (e.g., logs, ISO templates) on ESXi datastores, followed by beaconing or POST operations to external IPs potentially hiding payloads in file-like traffic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0654 - AN0654"*

Table 6942. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0235#AN0654

Analytic 0645 - AN0645

Detects adversarial abuse of systemd timers by correlating file creation/modification of .timer and .service units in system directories with the execution of abnormal child processes launched by 'systemd' (PID 1), especially as root.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0645 - AN0645"*

Table 6943. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0231#AN0645

Analytic 0456 - AN0456

Chain: (1) interactive/non-interactive `chage -l`, `grep`/`cat` of PAM config (e.g., `/etc/pam.d/common-password`, `/etc/security/pwquality.conf`); (2) optional reads of `/etc/login.defs`; (3) same user performs account enumeration or password change attempts shortly after. Use auditd `execve` and file read events plus shell history collection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0456 - AN0456"*

Table 6944. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0161#AN0456

Analytic 0546 - AN0546

Detects PAM module modifications or removal of MFA hooks in /etc/pam.d/ configurations, correlated with successful authentications lacking MFA prompts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0546 - AN0546"*

Table 6945. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0190#AN0546

Analytic 0564 - AN0564

Suspicious outbound HTTPS connections where the TLS Server Name Indication (SNI) does not match the HTTP Host header, indicating potential use of domain fronting to mask C2 traffic via CDNs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0564 - AN0564"*

Table 6946. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0196#AN0564

Analytic 0547 - AN0547

Detects modifications to authorization plugins responsible for MFA enforcement and correlates with suspicious login sessions missing MFA prompts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0547 - AN0547"*

Table 6947. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0190#AN0547

Analytic 0457 - AN0457

Chain: (1) execution of `pwpolicy` or MDM/DirectoryService reads of account policies; (2) optional read of `/Library/Preferences/com.apple.loginwindow` or config profiles; (3) follow-on credential probing or lateral movement by same user/session. Use unified logs and process telemetry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0457 - AN0457"*

Table 6948. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0161#AN0457

Analytic 0475 - AN0475

Direct write access to /dev/mem or /sys/firmware combined with usage of firmware flashing utilities (e.g., flashrom).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0475 - AN0475"*

Table 6949. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0167#AN0475

Analytic 0745 - AN0745

High CPU usage by unauthorized containers running mining binaries or public proxy tools.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0745 - AN0745"*

Table 6950. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0267#AN0745

Analytic 0754 - AN0754

vSphere API logins (vimService) or SSH to ESXi host followed by unauthorized shell commands or lateral remote logins from the ESXi host.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0754 - AN0754"*

Table 6951. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0269#AN0754

Analytic 0574 - AN0574

Detects enumeration of VMs using PowerShell (`Get-VM`), VMware Workstation (`vmrun.exe`), or Hyper-V (`VBoxManage.exe`). Defender observes suspicious command lines executed by unexpected users or outside normal administrative sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0574 - AN0574"*

Table 6952. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0199#AN0574

Analytic 0458 - AN0458

Chain: (1) cloud API calls that fetch tenant/organization password policy (e.g., AWS `GetAccountPasswordPolicy`, GCP/OCI equivalents or IAM settings reads); (2) within a short window, the same principal creates users, rotates creds, or changes auth settings. Use cloud audit logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0458 - AN0458"*

Table 6953. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0161#AN0458

Analytic 0584 - AN0584

Excessive resource exhaustion or service crash induced by processes launched by users or scripts that rapidly consume CPU/memory or attempt malformed service interactions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0584 - AN0584"*

Table 6954. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0208#AN0584

Analytic 0485 - AN0485

On Linux, defenders may observe forged cookie activity as unauthorized modifications to browser cookie databases (e.g., ~/.mozilla/firefox/*/cookies.sqlite, ~/.config/chromium/Default/Cookies) or scripted injection of session tokens. Suspicious usage includes curl/wget commands embedding forged cookies in headers, correlated with abnormal session activity in SaaS or IaaS logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0485 - AN0485"*

Table 6955. Table References

https://attack.mitre.org/detectionstrategies/DET0211#AN0594

Analytic 0945 - AN0945

Detects user or root invocation of `at` command to schedule a job, followed by job execution using LaunchServices and activity in /usr/lib/cron/at.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0945 - AN0945"*

Table 6962. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0333#AN0945

Analytic 0495 - AN0495

Detects exploitation attempts against macOS authentication frameworks such as OpenDirectory or Keychain. Defender perspective includes abnormal crashes in opendirectoryd, unauthorized Keychain API usage, and unusual sudo or login events. Correlation links unexpected process behavior with credential access anomalies.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0495 - AN0495"*

Table 6963. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0174#AN0495

Analytic 0954 - AN0954

Use of stolen Kerberos tickets or token impersonation resulting in logon sessions from accounts without expected interactive logon events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0954 - AN0954"*

Table 6964. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0338#AN0954

Analytic 0466 - AN0466

Detects adversary behavior where the command-line arguments of a running process are overwritten in memory to spoof the process name, typically replacing it with a benign or misleading string. The detection correlates unexpected null byte sequences, discrepancies between `/proc/<pid>/cmdline` and process ancestry, and suspicious memory writes shortly after process start.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0466 - AN0466"*

Table 6965. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0164#AN0466

Analytic 0664 - AN0664

Adversary modifies internal or external site content through manipulated application bundles, hosted content, or web server configs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0664 - AN0664"*

Table 6966. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0238#AN0664

Analytic 0646 - AN0646

Detects anomalous usage of ESXi Guest Operations APIs such as StartProgramInGuest, ListProcessesInGuest, ListFileInGuest, or InitiateFileTransferFromGuest. Defender perspective focuses on unusual frequency of guest API calls, invocation from unexpected management accounts, or execution outside of business hours. These correlated signals indicate adversarial abuse of ESXi administrative services to run commands on guest VMs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0646 - AN0646"*

Table 6967. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0232#AN0646

Analytic 0467 - AN0467

Detects adversary behavior clearing command history via `history -c`, deletion or modification of ~/.bash_history, or manipulation of the HISTFILE environment variable post-login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0467 - AN0467"*

Table 6968. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0165#AN0467

Analytic 0647 - AN0647

Defenders may observe adversary attempts to collect or export full device configurations by detecting unusual SNMP queries, Smart Install (SMI) activity, or CLI/API commands that request running or startup configuration dumps. Correlated behaviors include high-volume read requests

for sensitive OIDs, repeated use of 'show running-config' or equivalent commands from untrusted IPs, or unexpected TFTP/SCP/FTP transfers containing configuration files. These behaviors often appear in sequence: anomalous authentication or privilege escalation, followed by bulk configuration retrieval and outbound transfer.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0647 - AN0647"*

Table 6969. Table References

Analytic 0557 - AN0557

Monitor sensitive data files such as plist-based storage, mail archives, or Office files for unexpected modifications. Detect anomalous processes modifying stored data outside expected update cycles using FSEvents and Unified Logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0557 - AN0557"*

Table 7017. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0193#AN0557

Analytic 0575 - AN0575

Detects VM enumeration attempts using virtualization utilities such as VirtualBox (`VBoxManage`) or Parallels CLI. Defender observes abnormal invocation of VM listing commands correlated with non-admin users or unusual parent processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0575 - AN0575"*

Table 7018. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0199#AN0575

Analytic 0755 - AN0755

Adversary modifies Group Policy Objects (GPOs), domain trust, or directory service objects via GUI, CLI, or programmatic APIs. Behavior includes creation/modification of GPOs, delegation permissions, trust objects, or rogue domain controller registration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0755 - AN0755"*

Table 7019. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0270#AN0755

Analytic 0855 - AN0855

Defender observes configuration changes on firewall/network appliance involving rule creation, modification, or deletion from abnormal management IPs or non-console channels (e.g., remote CLI, API). These are often correlated with a spike in previously blocked outbound traffic, unexpected allow-all rules, or bulk rule deletions. Behavior often follows unauthorized login, privilege escalation, or API abuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0855 - AN0855"*

Table 7020. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0306#AN0855

Analytic 0558 - AN0558

Execution of control.exe or rundll32.exe with parameters pointing to CPL files, especially from non-standard directories or newly created files, followed by suspicious child process execution or registry modifications registering new Control Panel items.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0558 - AN0558"*

Table 7021. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0194#AN0558

Analytic 0585 - AN0585

Malicious script or binary causes repeated kernel panics, OOM kills, or systemd service restarts targeting services like nginx, httpd, sshd.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0585 - AN0585"*

Table 7022. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0208#AN0585

Analytic 0595 - AN0595

Adversary modifies or replaces the Terminal Services DLL (`termsrv.dll`) or changes the associated `ServiceDll` Registry value to load an arbitrary or patched DLL that enables persistent and enhanced RDP access. This may include binary replacement, registry tampering, and unexpected module loads by the `svchost.exe -k termsvcs` process.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0595 - AN0595"*

Table 7023. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0212#AN0595

Analytic 0559 - AN0559

Execution of built-in tools (e.g., ipconfig, route, netsh) or PowerShell/WMI queries to enumerate IP, MAC, interface status, or routing configuration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0559 - AN0559"*

Table 7024. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0195#AN0559

Analytic 0955 - AN0955

Access tokens or SSH keys used without corresponding login shell or PAM module activity, particularly for remote execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0955 - AN0955"*

Table 7025. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0338#AN0955

Analytic 0656 - AN0656

Phishing attachments executed on Linux systems are detected by linking email logs to file creation in mail directories and subsequent suspicious process execution. Look for unexpected binaries or scripts spawned from user mail directories and anomalous outbound network activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0656 - AN0656"*

Table 7026. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0236#AN0656

Analytic 0665 - AN0665

Adversary defaces internal VM-hosted portals or web UIs by modifying static content on datastore-mounted paths.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0665 - AN0665"*

Table 7027. Table References

https://attack.mitre.org/detectionstrategies/DET0238#AN0665

Analytic 0566 - AN0566

Unsigned or user-space apps initiate TLS connections with one hostname and HTTP headers requesting a different domain, commonly abused in CDN-resident domain fronting techniques.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0566 - AN0566"*

Table 7028. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0196#AN0566

Analytic 0765 - AN0765

Correlates creation/modification of systemd service files or /etc/init.d scripts with outlier process behavior during boot

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0765 - AN0765"*

Table 7029. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0274#AN0765

Analytic 0567 - AN0567

Traffic originating from ESXi hosts or management interfaces displays SNI-to-Host mismatch behavior, particularly anomalous given typical infrastructure communication patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0567 - AN0567"*

Table 7030. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0196#AN0567

Analytic 0756 - AN0756

Adversary modifies tenant policy through changes to federation configuration, trust settings, or identity provider additions in Microsoft 365/AzureAD via Portal, PowerShell, or Graph API. Includes setting authentication to federated or updating federated domains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0756 - AN0756"*

Table 7031. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0270#AN0756

Analytic 0657 - AN0657

Phishing attachment detection on macOS through correlation of Mail app logs, file creation in user directories, and abnormal process execution (e.g., Preview.app or Mail.app spawning Terminal or scripting binaries). Network traffic after attachment interaction is also monitored.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0657 - AN0657"*

Table 7032. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0236#AN0657

Analytic 0675 - AN0675

Detects forged Kerberos Silver Tickets by identifying anomalous Kerberos service ticket activity

such as malformed fields in logon events, TGS requests without interaction with the KDC, and access attempts using service accounts outside expected hosts/resources. Also monitors suspicious processes accessing LSASS memory for credential dumping.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0675 - AN0675"*

Table 7033. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0241#AN0675

Analytic 0576 - AN0576

Cause→effect chain: (1) A user or service launches an indirection utility (e.g., forfiles.exe, pcalua.exe, wsl.exe, scriptrunner.exe, ssh.exe with -o ProxyCommand/LocalCommand). (2) That utility spawns a secondary program/command (PowerShell, cmd, msiexec, regsvr32, curl, arbitrary EXE) and/or opens outbound network connections. (3) Optional precursor modification of SSH config to persist LocalCommand/ProxyCommand. Correlate process creation, command/script content, file access to %USERPROFILE%\.ssh\config, and network connections from the utility or its child.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0576 - AN0576"*

Table 7034. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0200#AN0576

Analytic 0856 - AN0856

Correlated file access to insecure credential files (e.g., *.env, *.xml, *.ps1) followed by suspicious process execution or authentication using retrieved credentials. Detected through Sysmon logs and Windows Security Event logs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0856 - AN0856"*

Table 7035. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0307#AN0856

Analytic 0568 - AN0568

A non-standard process (or script-hosted process) loads camera/video-capture libraries (e.g., avicap32.dll, mf.dll, ksproxy.ax), opens the Camera Frame Server/device, writes video/image artifacts (e.g., .mp4/.avi/.yuv) to unusual locations, and optionally initiates outbound transfer shortly after.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0568 - AN0568"*

Table 7036. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0197#AN0568

Analytic 0865 - AN0865

Detects unauthorized additions of users or machine accounts to privileged local or domain groups (e.g., Administrators, Remote Desktop Users).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0865 - AN0865"*

Table 7037. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0310#AN0865

Analytic 0586 - AN0586

Adversary launches high-entropy process or malformed app bundle causing repeated application crashes and system slowdowns.

Table 7042. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0338#AN0956

Analytic 0965 - AN0965

Detection of clipboard access via OS utilities (e.g., clip.exe, Get-Clipboard) by non-interactive or abnormal parent processes, potentially chained with staging or exfiltration commands.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0965 - AN0965"*

Table 7043. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0341#AN0965

Analytic 0659 - AN0659

Detection of edits or additions to /etc/rc.common, /Library/StartupItems, or /System/Library/StartupItems and associated script execution during login or reboot.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0659 - AN0659"*

Table 7044. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0237#AN0659

Analytic 0695 - AN0695

Detects adversarial use of cloud-native APIs (e.g., AWS IAM, Azure RBAC, GCP Identity) to enumerate cloud group memberships or policy mappings via unauthorized sessions or scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0695 - AN0695"*

Table 7045. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0251#AN0695

Analytic 0569 - AN0569

A process opens/reads /dev/video* (V4L2), performs ioctl/read loops, writes large/continuous video artifacts to disk, and/or quickly establishes outbound connections for exfiltration.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0569 - AN0569"*

Table 7046. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0197#AN0569

Analytic 0775 - AN0775

Detection of writes to /boot or EFI directories outside of expected package manager updates. Monitoring kernel log and auditd events for attempts to overwrite bootloader binaries (e.g., grub, shim). Unexpected execution of efibootmgr or dd writing to /dev/sdX devices followed by boot parameter changes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0775 - AN0775"*

Table 7047. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0278#AN0775

Analytic 0757 - AN0757

Detects anomalous process access to LSASS on domain controllers, suspicious module loads of

authentication DLLs, and registry or file modifications indicative of Skeleton Key–style patching. Correlates LSASS access attempts with subsequent abnormal logon activity patterns.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0757 - AN0757"*

Table 7048. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0271#AN0757

Analytic 0577 - AN0577

DLL hijacking behaviors including unexpected DLL loads from non-standard directories, replacement of DLLs, phantom DLL insertion, redirection file creation, and substitution of legitimate DLLs. Defender correlates file system modifications, registry changes, and module load telemetry to detect abnormal DLL behavior in trusted processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0577 - AN0577"*

Table 7049. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0201#AN0577

Analytic 0758 - AN0758

Detects unauthorized modification of network device authentication by correlating OS image file changes, checksum mismatches, or memory verification failures with anomalous authentication events. Focus is on behaviors where patched images introduce hardcoded passwords or bypass native authentication.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0758 - AN0758"*

Table 7050. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0272#AN0758

Analytic 0587 - AN0587

Instance enters degraded/unhealthy state due to abnormal process load or memory exhaustion, often caused by automation or script-based attacks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0587 - AN0587"*

Table 7051. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0208#AN0587

Analytic 0785 - AN0785

Detection focuses on identifying anomalous regsvr32.exe executions that deviate from normal administrative or system use. Defenders may observe regsvr32.exe loading scriptlets or DLLs from unusual paths (especially temporary directories or remote URLs), command-line arguments invoking /i or /u with suspicious file references, network connections initiated by regsvr32.exe, and unsigned or untrusted DLLs being loaded shortly after regsvr32.exe invocation. Correlated sequences include regsvr32.exe process creation, module load of DLL/scriptlet, and optional outbound network traffic.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0785 - AN0785"*

Table 7052. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0282#AN0785

Analytic 0578 - AN0578

Detects interactive or scripted abuse of cmd.exe, batch files, or shell invocation chains. Focuses on parent-child relationships (e.g., cmd.exe launched from unusual parents), anomalous command-line parameters, and chaining with discovery, credential access, or lateral movement behaviors.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0578 - AN0578"*

Table 7053. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0202#AN0578

Analytic 0857 - AN0857

File reads or process executions involving insecurely stored credential files (e.g., config files with password fields) by non-root or anomalous users followed by ssh authentication attempts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0857 - AN0857"*

Table 7054. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0307#AN0857

Analytic 0875 - AN0875

Detects suspicious execution of network monitoring tools (e.g., Wireshark, tshark, Microsoft Message Analyzer), driver loading indicative of promiscuous mode, or non-admin user privilege escalation to access NICs for capture.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0875 - AN0875"*

Table 7055. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0314#AN0875

Analytic 0975 - AN0975

Correlate registry modifications (e.g., UAC bypass registry keys), unusual parent-child process relationships (e.g., control.exe spawning cmd.exe), and unsigned elevated process executions with non-standard tokens or elevation flags.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0975 - AN0975"*

Table 7056. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0345#AN0975

Analytic 0795 - AN0795

Monitor SaaS mail platforms (Google Workspace, M365, Okta-integrated apps) for SendAs/SendOnBehalfOf operations where the delegated permissions are unusual or newly granted. Detect impersonation attempts where adversaries configure rules to auto-forward or auto-reply with impersonated content.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0795 - AN0795"*

Table 7057. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0286#AN0795

Analytic 0597 - AN0597

Outbound connections from non-network-facing processes repeatedly send similarly sized payloads within uniform time intervals.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0597 - AN0597"*

Table 7058. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0213#AN0597

Analytic 0957 - AN0957

Unusual reuse of OAuth access tokens from different geographic regions, without full login events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0957 - AN0957"*

Table 7059. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0338#AN0957

Analytic 0759 - AN0759

Processes that normally do not initiate network connections establishing outbound encrypted TLS/SSL sessions, especially with asymmetric traffic volumes (client sending more than receiving) or non-standard certificate chains. Defender observations correlate process creation with unexpected network encryption libraries being loaded.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0759 - AN0759"*

Table 7060. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0273#AN0759

Analytic 0579 - AN0579

Detects ptrace-based process injection by correlating audit logs of ptrace syscalls, memory modifications (e.g., poketext, pokedata), and suspicious register manipulation on a target process not normally debugged by the originator. Alerts on processes attempting to ptrace non-child or privileged processes, especially those followed by abnormal memory or execution behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0579 - AN0579"*

Table 7061. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0203#AN0579

Analytic 0588 - AN0588

Container orchestrator logs show crashlooping pods, repeated resource exhaustion, or malicious binaries with infinite loops consuming systemd/cgroup limits.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0588 - AN0588"*

Table 7062. Table References

https://attack.mitre.org/detectionstrategies/DET0338#AN0959

Analytic 0599 - AN0599

Detection of executables or scripts containing hidden embedded resources or secondary payloads, often with anomalies in file size vs. functionality or dropped child binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0599 - AN0599"*

Table 7072. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0214#AN0599

Analytic 0995 - AN0995

Detection of processes launching downgraded PowerShell versions (e.g., v2) or other legacy binaries that lack logging or security features. Correlates command-line arguments, process metadata, and version fields. Monitors registry changes to Defender or HVCI keys that could indicate intentional downgrades.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0995 - AN0995"*

Table 7073. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0350#AN0995

Analytic 0666 - AN0666

Adversary uses compromised instance credentials or web application access to deface content hosted in S3 buckets, Azure Blob Storage, or GCP Buckets.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0666 - AN0666"*

Table 7074. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0238#AN0666

Analytic 0676 - AN0676

Unusual database command-line access (e.g., `psql`, `mysql`, `mongo`) from non-admin users, occurring outside typical automation windows or without known service context. Often followed by data dumps to .sql/.csv files or outbound data transfers. Defender sees CLI tools launched interactively or by unusual parent processes, file writes to dump-like filenames, and external connections shortly after.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0676 - AN0676"*

Table 7075. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0242#AN0676

Analytic 0667 - AN0667

Correlates registry modifications to EventLog or WMI Autologger keys, suspicious use of Set-EtwTraceProvider, and Sysmon configuration changes. Defender sees interruption or redirection of ETW and log event collection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0667 - AN0667"*

Table 7076. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0239#AN0667

Analytic 0766 - AN0766

Observes creation or modification of LaunchAgent/LaunchDaemon property list files combined with anomalous plist payload execution after user logon

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0766 - AN0766"*

Table 7077. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0274#AN0766

Analytic 0686 - AN0686

Correlate MFA push fatigue or unusual consent grant attempts with call activity where adversaries may have socially engineered the user over voice.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0686 - AN0686"*

Table 7078. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0245#AN0686

Analytic 0668 - AN0668

Detects disabling or reconfiguration of syslog or rsyslog services. Monitors sudden stops in logging daemons and suspicious execution of kill or service stop commands targeting syslog processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0668 - AN0668"*

Table 7079. Table References

https://attack.mitre.org/detectionstrategies/DET0239#AN0668

Analytic 0866 - AN0866

Detects unexpected use of usermod, gpasswd, or direct modification of /etc/group to elevate user group membership.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0866 - AN0866"*

Table 7080. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0310#AN0866

Analytic 0966 - AN0966

Detection of pbpaste/pbcopy clipboard access by processes without terminal sessions or linked to launch agents, potentially staged for collection.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0966 - AN0966"*

Table 7081. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0341#AN0966

Analytic 0669 - AN0669

Detection of tampering with Apple's Unified Logging framework or modification of system log forwarding settings. Defender observes execution of logd-related commands or defaults write to logging preferences.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0669 - AN0669"*

Table 7082. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0239#AN0669

Analytic 0696 - AN0696

Identifies unauthorized access or enumeration of administrative roles, security groups, or distribution groups via Exchange/SharePoint/Teams APIs or role discovery scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0696 - AN0696"*

Table 7083. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0251#AN0696

Analytic 0776 - AN0776

Abnormal modification of EFI firmware binaries in /System/Library/CoreServices/ or NVRAM parameters not associated with OS updates. Unified logs capturing calls to bless or nvram commands executed from untrusted parent processes. Sudden unsigned kext loads after EFI variable tampering.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0776 - AN0776"*

Table 7084. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0278#AN0776

Analytic 0767 - AN0767

An adversary leverages built-in tools such as certutil.exe, powershell.exe, or copy.exe to decode, reassemble, or extract hidden malicious content from obfuscated containers or encoded formats. The decoding utility often spawns shortly after file staging or download and may be chained with script interpreters or further payload execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0767 - AN0767"*

Table 7085. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0275#AN0767

Analytic 0677 - AN0677

Database client execution (e.g., sqlcmd.exe, isql.exe) by users or from locations not tied to enterprise automation or backups. Often followed by creation of .sql/.bak/.csv files, registry artifacts for ODBC/JDBC drivers, or encrypted ZIPs. Defender sees SQL tools launched by explorer.exe, Powershell, or odd parent processes, plus file writes in user temp locations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0677 - AN0677"*

Table 7086. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0242#AN0677

Analytic 0876 - AN0876

Correlates interface mode changes to promiscuous with execution of sniffing tools like tcpdump, tshark, or custom pcap libraries. Detects abnormal NIC configurations and unauthorized sniffing from non-root sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0876 - AN0876"*

Table 7087. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0314#AN0876

Analytic 0867 - AN0867

Detects use of `dseditgroup` or `dscl` to add users to privileged macOS groups (e.g., admin).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0867 - AN0867"*

Table 7088. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0310#AN0867

Analytic 0678 - AN0678

Execution of Java-based or CLI database tools (e.g., DBeaver, Beekeeper, mysql, psql) from user profiles not tied to dev/admin roles, especially when followed by file writes and cloud sync activity. Defender correlates GUI tool launches, file write events in ~/Downloads or ~/Documents, and outbound API calls to known cloud services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0678 - AN0678"*

Table 7089. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0242#AN0678

Analytic 0687 - AN0687

Behavior chain involving unexpected API calls to capture keyboard input, driver loads for keyloggers, or remote use of smart card authentication via logon sessions not initiated by local user interaction

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0687 - AN0687"*

Table 7090. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0246#AN0687

Analytic 0768 - AN0768

The adversary uses native utilities like base64, gzip, tar, or openssl to decode, decompress, or decrypt files that were previously staged or downloaded. These tools may be chained with curl/wget and executed via bash/zsh, often to extract an embedded payload or reverse shell script.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0768 - AN0768"*

Table 7091. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0275#AN0768

Analytic 0786 - AN0786

Detection of suspicious token manipulation chains: use of token-related APIs (e.g., LogonUser, DuplicateTokenEx) or commands (runas) → spawning of a new process under a different security context (e.g., SYSTEM) → mismatched parent-child process lineage or anomalies in Event Tracing for Windows (ETW) token/PPID data → abnormal lateral or privilege escalation activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0786 - AN0786"*

Table 7092. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0283#AN0786

Analytic 0769 - AN0769

The adversary invokes built-in scripting or decoding tools like base64, plutil, or AppleScript-based utilities to decode files embedded in staging artifacts. Decoding often occurs post-download or as

part of post-exploitation payload deployment via zsh, python, or osascript.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0769 - AN0769"*

Table 7093. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0275#AN0769

Analytic 0679 - AN0679

Database enumeration and export activity (e.g., `SELECT * FROM`, `SHOW DATABASES`) issued via ephemeral VMs, admin APIs, or cloud shell from non-monitoring accounts. Defender correlates audit logs (CloudTrail, GCP Admin, AzureDiagnostics), storage write ops, and cross-region transfers by identities not tied to DB operations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0679 - AN0679"*

Table 7094. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0242#AN0679

Analytic 0796 - AN0796

Monitor Office Suite applications (Outlook, Word mail merge, Excel macros) for abnormal automated message sending, especially when macros or scripts trigger email delivery. Detect patterns of impersonation language (urgent, payment, executive request) combined with anomalous execution of Office macros.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0796 - AN0796"*

Table 7095. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0286#AN0796

Analytic 0697 - AN0697

Monitors API calls and service-specific logs for enumeration of organizational roles, permissions, and group structure, particularly outside of normal admin behavior baselines.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0697 - AN0697"*

Table 7096. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0251#AN0697

Analytic 0976 - AN0976

Monitor audit logs for setuid/setgid bit changes, executions where UID ≠ EUID (indicative of sudo or privilege escalation), and high-integrity binaries launched by unprivileged users.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0976 - AN0976"*

Table 7097. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0345#AN0976

Analytic 0967 - AN0967

Detection of xclip or xsel access to clipboard buffers outside of user terminal context, especially when chained to staging (gzip, base64) or network exfiltration (curl, scp).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0967 - AN0967"*

Table 7098. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0341#AN0967

Analytic 0868 - AN0868

Detection of inconsistencies between reported sensor health and actual process/service state. For example, Windows Defender tray icon/UI showing healthy status while corresponding Defender services (WinDefend, MsMpEng) are stopped or disabled. Correlates process creation events with missing or terminated security processes and spoofed health events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0868 - AN0868"*

Table 7099. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0311#AN0868

Analytic 0688 - AN0688

Detection of unauthorized keylogger behavior through access to `/dev/input`, loading kernel modules (e.g., via insmod), or polling user input devices from non-user shells

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0688 - AN0688"*

Table 7100. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0246#AN0688

Analytic 0886 - AN0886

Unusual service stop events, termination of AV/EDR processes, registry modifications disabling security tools, and firewall/defender configuration changes. Correlate process creation with service stop requests and registry edits.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0886 - AN0886"*

Table 7101. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0886

Analytic 0698 - AN0698

User-initiated installation of Python (pip), NodeJS (npm), or other language libraries, followed by unexpected network connections, credential access, or startup file modifications. Defender sees `pip install` or `npm install` commands run by a non-root user, followed shortly by new `.py`, `.sh`, or `.js` files in hidden directories, or interpreter-based execution during boot/login.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0698 - AN0698"*

Table 7102. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0252#AN0698

Analytic 0968 - AN0968

Execution of hh.exe to open a .chm file followed by suspicious child processes or script engine invocation (VBScript, JScript, mshta, powershell). Behavior includes loading a CHM file from untrusted locations, or immediately spawning commands indicative of payload execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0968 - AN0968"*

Table 7103. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0342#AN0968

Analytic 0689 - AN0689

Processes accessing TCC-protected input APIs or polling HID services without user interaction, or dynamically loaded keylogging frameworks using accessibility privileges

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0689 - AN0689"*

Table 7104. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0246#AN0689

Analytic 0896 - AN0896

Processes like git, curl, or python scripts executing commands that package files (tar, gzip) followed by HTTPS uploads to code repository endpoints. Defender view: detect unusual git push activity or scripted HTTPS requests outside normal developer work hours.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0896 - AN0896"*

Table 7105. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0318#AN0896

Analytic 0986 - AN0986

Detects malicious containers or pods using names, labels, or namespaces that mimic legitimate workloads; also checks for image layer mismatches and unauthorized resource deployments.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0986 - AN0986"*

Table 7106. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0347#AN0986

Analytic 0869 - AN0869

Monitoring for discrepancies between system daemon/service state and reported health messages (e.g., syslog shows AV/IDS daemon stopped, but spoofed messages claim it is still running). Detects userland processes impersonating AV/IDS command-line outputs or modifying log forwarding configurations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0869 - AN0869"*

Table 7107. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0311#AN0869

Analytic 0699 - AN0699

Execution of `pip.exe`, `npm.cmd`, or MSI installers within user context, followed by script interpreter startup (e.g., python.exe) or PowerShell with unusual child processes or file writes in `%APPDATA%`,

`%TEMP%`, or `%LOCALAPPDATA%`. Defender correlates command-line install tools with Sysmon and Event Logs to trace downstream behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0699 - AN0699"*

Table 7108. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0252#AN0699

Analytic 0969 - AN0969

High-volume packet generation by local processes (e.g., PowerShell, cmd, curl.exe) or network service processes resulting in excessive outbound traffic over short time window, correlated with abnormal resource usage or degraded host responsiveness.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0969 - AN0969"*

Table 7109. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0343#AN0969

Analytic 0996 - AN0996

Monitors execution of older or legacy interpreters (e.g., python2, bash with restricted history logging), downgrade of TLS/SSL configurations, or forced fallback to unencrypted protocols. Detects suspicious reconfiguration of kernel modules or boot loaders to reduce integrity controls.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0996 - AN0996"*

Table 7110. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0350#AN0996

Analytic 0777 - AN0777

Unexpected firmware image uploads via TFTP/FTP/SCP. Configuration changes modifying boot image pointers. Logs showing boot variable redirection to non-standard images. Anomalous reboots immediately following firmware changes not tied to patch schedules.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0777 - AN0777"*

Table 7111. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0278#AN0777

Analytic 0877 - AN0877

Detects enabling of interface sniffing via packet capture tools or AppleScript triggering `tcpdump`. Leverages Unified Logs and process lineage to identify suspicious use of `pfctl`, `tcpdump`, or `libpcap` libraries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0877 - AN0877"*

Table 7112. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0314#AN0877

Analytic 0787 - AN0787

Unexpected processes (e.g., powershell.exe, wscript.exe, office apps) initiating HTTP POST/PUT requests to text storage domains like pastebin.com or hastebin.com, particularly when preceded by file access in sensitive directories. Defender perspective: correlation of process lineage, large clipboard/file read operations, and outbound uploads to text storage services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0787 - AN0787"*

Table 7113. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0284#AN0787

Analytic 0778 - AN0778

Monitor for abnormal creation or modification of Windows services (e.g., via sc.exe, PowerShell, or API calls) that load non-standard executables. Correlate registry changes in service keys with service creation events and process execution to detect service abuse for persistence or execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0778 - AN0778"*

Table 7114. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0279#AN0778

Analytic 0797 - AN0797

Cause→effect chain: (1) A client app (browser, Office, PDF/Flash/reader) experiences a crash/abnormal exit or loads from an unusual location, then (2) drops or modifies a file in user-writable paths, and/or (3) spawns an unexpected child (e.g., powershell/cmd/mshta/rundll32/wscript/installer), and (4) establishes outbound C2-like connections shortly after. Correlate application logs, file writes, process lineage, and network egress within a short window.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0797 - AN0797"*

Table 7115. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0287#AN0797

Analytic 0779 - AN0779

Detect unusual invocations of systemctl, service, or init scripts creating or modifying daemons. Monitor audit logs for execution of binaries from unexpected paths linked to service start/stop activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0779 - AN0779"*

Table 7116. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0279#AN0779

Analytic 0977 - AN0977

Detect execution of `/usr/libexec/security_authtrampoline` or use of AuthorizationExecuteWithPrivileges API, and monitor process lineage for unusual launches of GUI apps with escalated privileges.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0977 - AN0977"*

Table 7117. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0345#AN0977

Analytic 0887 - AN0887

Execution of commands that stop or kill processes associated with logging or security daemons (auditd, syslog, falco). Detect modifications to iptables or disabling SELinux/AppArmor enforcement. Correlate sudo/root context with abrupt service halts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0887 - AN0887"*

Table 7118. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0887

Analytic 0878 - AN0878

Detects creation of traffic mirroring sessions (e.g., AWS VPC Traffic Mirroring, Azure vTAP) that redirect traffic from critical assets to other virtual instances, often followed by file creation or session establishment.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0878 - AN0878"*

Table 7119. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0314#AN0878

Analytic 0788 - AN0788

Use of curl, wget, or custom scripts to POST data to pastebin-like services. Defender perspective: identify chained behavior where files are compressed/read followed by HTTPS POST requests to text-sharing endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0788 - AN0788"*

Table 7120. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0284#AN0788

Analytic 0879 - AN0879

Detects execution of capture commands via CLI (`monitor capture`, `debug packet`, etc.) or unauthorized CLI access followed by logging configuration changes on Cisco/Juniper/Arista gear.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0879 - AN0879"*

Table 7121. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0314#AN0879

Analytic 0978 - AN0978

Monitor for unexpected privilege elevation operations via SAML assertion manipulation, role injection, or changes to identity mappings that result in access escalation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0978 - AN0978"*

Table 7122. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0345#AN0978

Analytic 0897 - AN0897

Office or scripting applications initiating unusual HTTPS traffic to code repository APIs with high outbound-to-inbound ratios. Defender perspective: monitor for sensitive file access in combination with network connections to github.com, gitlab.com, or bitbucket.org.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0897 - AN0897"*

Table 7123. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0318#AN0897

Analytic 0798 - AN0798

Cause→effect chain: (1) Browser/Office/reader process logs crash/segfault or abnormal sandbox message, (2) new executable/script/write occurs in $HOME (Downloads, ~/.cache, /tmp), (3) unexpected child like curl/wget/bash/python opens network connections soon after.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0798 - AN0798"*

Table 7124. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0287#AN0798

Analytic 0789 - AN0789

Processes such as osascript, curl, or office applications sending data to text storage APIs/domains. Defender perspective: anomalous clipboard or file reads by unexpected applications immediately followed by outbound HTTPS requests to pastebin-like services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0789 - AN0789"*

Table 7125. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0284#AN0789

Analytic 0987 - AN0987

Detects VIBs, scripts, or binaries placed into directories like /bin or /etc/vmware with names mimicking standard ESXi components. Also monitors unauthorized creation of services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0987 - AN0987"*

Table 7126. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0347#AN0987

Analytic 0997 - AN0997

Detection of execution of legacy scripting runtimes (e.g., older versions of Python, Bash, or PowerShell Core) lacking auditing. Monitoring for changes to EFI or system boot files indicative of downgrade-based persistence or bypass of integrity features.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0997 - AN0997"*

Table 7127. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0350#AN0997

Analytic 0799 - AN0799

Cause→effect chain: (1) App crash/abnormal termination in unified logs for Safari/Chrome/Office/Preview, (2) new files/scripts in ~/Library, ~/Downloads, /private/var/folders/*, (3) unexpected child (osascript, zsh, bash, curl) spawned by those apps, (4) new outbound connections.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0799 - AN0799"*

Table 7128. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0287#AN0799

Analytic 0979 - AN0979

Detect sudden privilege escalations such as IAM role changes, user-assigned privilege boundaries, or elevation via assumed roles beyond normal behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0979 - AN0979"*

Table 7129. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0345#AN0979

Analytic 0888 - AN0888

Execution of commands or APIs that disable Gatekeeper, XProtect, or system integrity protections. Detect configuration changes through unified logs. Monitor termination of system security

daemons (e.g., syspolicyd).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0888 - AN0888"*

Table 7130. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0888

Analytic 0988 - AN0988

Identifies suspicious outbound traffic volume mismatches from processes that typically do not generate network activity, particularly over C2 protocols like HTTPS, DNS, or custom TCP/UDP ports, following file or data access.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0988 - AN0988"*

Table 7131. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0348#AN0988

Analytic 0889 - AN0889

Modification of container runtime security profiles (AppArmor, seccomp) or removal of monitoring agents within containers. Detect unauthorized mounting/unmounting of host /proc or /sys to disable logging or auditing.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0889 - AN0889"*

Table 7132. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0317#AN0889

Analytic 0898 - AN0898

ESXi host processes (vmx, hostd) initiating HTTPS sessions toward external code repositories. Defender perspective: detect datastore reads followed by outbound web traffic inconsistent with administrative baselines.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0898 - AN0898"*

Table 7133. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0318#AN0898

Analytic 0899 - AN0899

Adversaries create user accounts via identity provider APIs or admin portals (e.g., Azure AD, Okta). These accounts may be assigned elevated privileges or used in chained authentication. Detection monitors Add User activity from suspicious IPs or automation sources, followed by role/permission escalation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0899 - AN0899"*

Table 7134. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0319#AN0899

Analytic 0989 - AN0989

Monitors for processes reading sensitive files then immediately initiating unusual outbound connections or bulk transfer sessions over persistent sockets, particularly with encrypted or binary payloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0989 - AN0989"*

Table 7135. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0348#AN0989

Analytic 0998 - AN0998

Linux permission escalation behavioral chain: (1) Process creation of permission modification utilities (chmod, chown, chgrp, setfacl) with suspicious parameters indicating privilege escalation intent, (2) System call analysis revealing direct file metadata manipulation (chmod, fchmod, chown, fchown syscalls), (3) Extended attribute and ACL modifications targeting critical system paths, (4) Temporal correlation with subsequent file access or process execution from modified locations, (5) Anomalous permission patterns deviating from system baselines

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0998 - AN0998"*

Table 7136. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0351#AN0998

Analytic 0999 - AN0999

macOS permission and attribute manipulation behavioral chain: (1) Process execution of permission utilities (chmod, chown, chgrp) or macOS-specific tools (chflags) with suspicious parameters, (2) System Integrity Protection (SIP) bypass attempts through permission

modifications, (3) File flags manipulation (uchg, schg, hidden) for evasion or persistence, (4) Extended attribute (xattr) modifications affecting security metadata, (5) Unified log correlation with file system events and subsequent access patterns, (6) Gatekeeper and code signing bypass through permission/attribute manipulation

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 0999 - AN0999"*

Table 7137. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0351#AN0999

Analytic 1111 - AN1111

Detects abuse of AuthorizationExecuteWithPrivileges API to gain elevated privileges via user credential prompts, typically through invocation of /usr/libexec/security_authtrampoline. Detection involves correlation of API usage, binary reputation, and prompt context.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1111 - AN1111"*

Table 7138. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0395#AN1111

Analytic 1112 - AN1112

Detects suspicious access to macOS Keychain files and APIs. Observes processes invoking the 'security' utility or accessing Keychain databases directly, correlates these with abnormal parent process lineage or unexpected user context. Monitors attempts to dump, unlock, or read credential storage beyond normal application workflows.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1112 - AN1112"*

Table 7139. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0396#AN1112

Analytic 1211 - AN1211

Modification or replacement of service executables due to weak file or directory permissions. Defender observes file writes to service binary paths, unexpected modifications of executables associated with registered services, and subsequent service execution of attacker-supplied binaries under elevated permissions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1211 - AN1211"*

Table 7140. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0436#AN1211

Analytic 1121 - AN1121

Detects high-frequency or anomalous DNS queries initiated by non-browser, non-system processes (e.g., PowerShell, rundll32, python.exe) used to establish command and control via DNS tunneling.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1121 - AN1121"*

Table 7141. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0400#AN1121

Analytic 1113 - AN1113

Detection of automated tools or scripts periodically transmitting data to external destinations using scheduled tasks or background processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1113 - AN1113"*

Table 7142. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0397#AN1113

Analytic 1131 - AN1131

Configuration changes to virtual TAP/mirror policies that forward traffic to unapproved destinations. Detection correlates management plane API calls with mirrored traffic observation.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1131 - AN1131"*

Table 7143. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0403#AN1131

Analytic 1311 - AN1311

Monitors Mail.app database or maildir file access, automation via AppleScript, and abnormal mail rule creation using scripting or UI automation frameworks.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1311 - AN1311"*

Table 7144. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0476#AN1311

Analytic 1114 - AN1114

Background scripts (e.g., via cron) or daemons transmitting data repeatedly to remote IPs or URLs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1114 - AN1114"*

Table 7145. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0397#AN1114

Analytic 1411 - AN1411

Adversary mounts external drive to /media or /mnt then accesses or copies targeted data via shell, cp, or tar.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1411 - AN1411"*

Table 7146. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0511#AN1411

Analytic 1141 - AN1141

Spoofed outbound packets sent to amplification services from command-line tools or scripts, combined with abnormal outbound packet volume on known reflector ports

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1141 - AN1141"*

Table 7147. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0408#AN1141

Analytic 1115 - AN1115

Observation of LaunchAgents or LaunchDaemons establishing periodic external connections indicative of automated data transfer.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1115 - AN1115"*

Table 7148. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0397#AN1115

Analytic 1151 - AN1151

Inspect network telemetry for adversary attempts to blend malicious traffic with legitimate flows using VPNs, proxies, or geolocation spoofing. Defensive teams may observe anomalous tunnels, encrypted sessions to suspicious domains, or geo-mismatched IP activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1151 - AN1151"*

Table 7149. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0411#AN1151

Analytic 1511 - AN1511

Processes that normally do not initiate network communications suddenly making outbound HTTPS connections with high outbound-to-inbound data ratios. Defender view: correlation between process creation logs (e.g., Word, Excel, PowerShell) and subsequent anomalous network traffic volumes toward common web services (Dropbox, Google Drive, OneDrive).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1511 - AN1511"*

Table 7150. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0548#AN1511

Analytic 1611 - AN1611

Detects credential dumping attempts targeting the NTDS.dit database by monitoring shadow copy creation, suspicious file access to %SystemRoot%\NTDS\ntds.dit, and the use of tooling like ntdsutil.exe or volume management APIs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1611 - AN1611"*

Table 7151. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0586#AN1611

Analytic 1161 - AN1161

Command-line tools (e.g., curl, rsync, wget, or custom Python scripts) used to scrape documentation systems or internal REST APIs. Unusual access patterns to knowledge base folders or shared team drives.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1161 - AN1161"*

Table 7152. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0413#AN1161

Analytic 1116 - AN1116

Office-based persistence via Office template macros, Outlook forms/rules/homepage, or registry-persistent scripts. Adversary modifies registry keys or Office application directories to load malicious scripts at startup.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1116 - AN1116"*

Table 7153. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0398#AN1116

Analytic 1117 - AN1117

Startup-based persistence mechanisms within Microsoft Office Suite like template macros and home page redirects being configured through internal automation or client-side settings.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1117 - AN1117"*

Table 7154. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0398#AN1117

Analytic 1171 - AN1171

Detects Automator, AppleScript, or Terminal executing curl, lftp, or TFTP for binary transfer to untrusted IPs or unusual ports.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1171 - AN1171"*

Table 7155. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0416#AN1171

Analytic 1711 - AN1711

The user can see persistent notifications in their notification drawer and can subsequently uninstall applications that do not belong. Applications could be vetted for their use of the

`startForeground()` API, and could be further scrutinized if usage is found.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1711 - AN1711"*

Table 7156. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0637#AN1711

Analytic 1181 - AN1181

Use ESXi syslogs to track abnormal DNS query patterns from management agents or VMs. Identify high-frequency, low-TTL, or unresolvable domains as suspicious. Correlate with unusual management plane process activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1181 - AN1181"*

Table 7157. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0419#AN1181

Analytic 1118 - AN1118

Recurring network exfiltration initiated by scheduled or script-based processes exhibiting time-based regularity and consistent external destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1118 - AN1118"*

Table 7158. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0399#AN1118

Analytic 1811 - AN1811

Network service scanning can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1811 - AN1811"*

Table 7159. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0696#AN1811

Analytic 1119 - AN1119

Detection of cron-based or script-based recurring transfers where the same script, user, or destination reappears at predictable intervals.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1119 - AN1119"*

Table 7160. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0399#AN1119

Analytic 1191 - AN1191

Detects user agents or background services making unauthorized or unscheduled web API calls to cloud/web services over HTTPS.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1191 - AN1191"*

Table 7161. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0425#AN1191

Analytic 1221 - AN1221

Detects the creation, modification, or deletion of scheduled tasks through Task Scheduler, WMI, PowerShell, or API-based methods followed by execution from svchost.exe or taskeng.exe. Includes detection of hidden or anomalous scheduled tasks, especially those created under SYSTEM or suspicious user contexts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1221 - AN1221"*

Table 7162. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0441#AN1221

Analytic 1212 - AN1212

Detects adversary activity aimed at accessing LSA Secrets, including registry key export of HKEY_LOCAL_MACHINE\SECURITY\Policy\Secrets or memory scraping via tools such as Mimikatz or PowerSploit's Invoke-Mimikatz.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1212 - AN1212"*

Table 7163. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0437#AN1212

Analytic 1122 - AN1122

Detects local daemons or scripts generating outbound DNS queries with long or frequent subdomains, indicative of DNS tunneling via tools like `iodine`, `dnscat2`, or `dig` from cronjobs or reverse shells.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1122 - AN1122"*

Table 7164. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0400#AN1122

Analytic 1132 - AN1132

Unauthorized mirroring sessions initiated on routers/switches (e.g., via `monitor session`, `mirror port`) coupled with outbound traffic from mirrored interface to unexpected destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1132 - AN1132"*

Table 7165. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0403#AN1132

Analytic 1312 - AN1312

Correlates unusual auto-forwarding rule creation via Exchange Web Services or Outlook rules engine, presence of X-MS-Exchange-Organization-AutoForwarded headers, and logon session anomalies from abnormal IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1312 - AN1312"*

Table 7166. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0476#AN1312

Analytic 1213 - AN1213

Detects suspicious custom compression/encryption routines through anomalous script or binary execution that produces high-entropy files without standard archiving utilities. Correlates script execution, memory API usage (bitwise ops, CryptoAPI calls), and creation of archive-like files with uncommon headers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1213 - AN1213"*

Table 7167. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0438#AN1213

Analytic 1123 - AN1123

Detects scripting environments (AppleScript, osascript, curl) or non-native tools performing DNS queries with encoded subdomains, often used for data exfiltration or beaconing.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1123 - AN1123"*

Table 7168. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0400#AN1123

Analytic 1321 - AN1321

Detects tampering of IIS-based login pages (e.g., default.aspx, login.aspx) tied to VPN, OWA, or SharePoint via script injection or unexpected editor processes modifying web roots.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1321 - AN1321"*

Table 7169. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0480#AN1321

Analytic 1231 - AN1231

AppleScript, LaunchAgents, or remote login services (`ssh`, `networksetup`) establishing proxy tunnels or dynamic port forwards to external IPs or alternate local hosts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1231 - AN1231"*

Table 7170. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0445#AN1231

Analytic 1421 - AN1421

Detects use of vulnerable kernel extensions or entitlements abused via setuid or AppleScript injection chains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1421 - AN1421"*

Table 7171. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0514#AN1421

Analytic 1214 - AN1214

Detects custom archive routines by correlating script execution (Python, Perl, Bash) with creation of high-entropy files in temporary or user directories. Flags processes performing unusual bitwise operations or writing files without standard compression headers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1214 - AN1214"*

Table 7172. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0438#AN1214

Analytic 1142 - AN1142

Command-line initiated UDP traffic bursts to external reflection amplification ports using built-in scripting or binaries with network anomalies

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1142 - AN1142"*

Table 7173. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0408#AN1142

Analytic 1412 - AN1412

Adversary attaches USB drive and accesses sensitive files using Finder, cp, or bash scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1412 - AN1412"*

Table 7174. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0511#AN1412

Analytic 1241 - AN1241

Detects the redirection of syscall execution flow via modification of VDSO code stubs or GOT entries to load and execute a malicious shared object through mmap and ptrace.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1241 - AN1241"*

Table 7175. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0448#AN1241

Analytic 1124 - AN1124

Detects clients issuing DNS queries with high volume, long subdomain lengths, encoded payload patterns, or to known malicious infrastructure; indicative of DNS-based C2 channels.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1124 - AN1124"*

Table 7176. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0400#AN1124

Analytic 1251 - AN1251

Detects suspicious changes to macOS authorization and PAM plugin files. Correlates file modifications under /etc/pam.d/ or /Library/Security/SecurityAgentPlugins with unexpected authentication attempts or anomalous account usage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1251 - AN1251"*

Table 7177. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0454#AN1251

Analytic 1125 - AN1125

Detects unusual outbound DNS traffic from ESXi hosts, often from shell scripts, custom daemons, or malicious VIBs interacting with external DNS infrastructure outside the management plane.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1125 - AN1125"*

Table 7178. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0400#AN1125

Analytic 1215 - AN1215

Detects custom archiving by monitoring execution of Swift/Objective-C apps or scripts producing high-entropy files with non-standard headers. Correlates unified logs of abnormal NSFileHandle/NSData operations, memory use of XOR/bitwise operations, and file creation events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1215 - AN1215"*

Table 7179. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0438#AN1215

Analytic 1152 - AN1152

Monitor VM-level DNS and network traffic logs for adversary-controlled domains or selective response behavior (e.g., dropped requests from security scanners).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1152 - AN1152"*

Table 7180. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0411#AN1152

Analytic 1521 - AN1521

Series of authentication failures (Event ID 4625) targeting the same or similar user accounts over time from one or more remote IPs

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1521 - AN1521"*

Table 7181. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0551#AN1521

Analytic 1512 - AN1512

Processes (tar, curl, python scripts) accessing large file sets and initiating outbound HTTPS POST requests with payload sizes inconsistent with baseline activity. Defender perspective: detect abnormal sequence of file archival followed by encrypted uploads to external web services.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1512 - AN1512"*

Table 7182. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0548#AN1512

Analytic 1621 - AN1621

Detects enabling of reversible password encryption in Active Directory or Group Policy, suspicious PowerShell commands modifying AD user properties, and unusual account configuration changes

correlated with policy modifications. Multi-event correlation links Group Policy edits, PowerShell command execution, and user account property changes to identify tampering with authentication encryption settings.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1621 - AN1621"*

Table 7183. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0589#AN1621

Analytic 1216 - AN1216

Detects the relocation of malicious executables via copy/move actions across suspicious folders (e.g., from Downloads to System32), followed by deletion of the original source or renaming to blend into legitimate binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1216 - AN1216"*

Table 7184. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0439#AN1216

Analytic 1162 - AN1162

Abuse of SaaS platforms such as Confluence, GitHub, SharePoint Online, or Slack to access excessive internal documentation or export source code/data. Includes use of tokens or browser automation from unapproved IPs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1162 - AN1162"*

Table 7185. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0413#AN1162

Analytic 1126 - AN1126

Creation or modification of `.plist` files in /Library/LaunchDaemons/, especially those with suspicious Program or ProgramArguments paths, combined with execution activity under launchd with elevated privileges. Detectable through correlated Unified Logs, file monitoring, and process telemetry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1126 - AN1126"*

Table 7186. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0401#AN1126

Analytic 1612 - AN1612

Detection of suspicious enumeration of local or domain accounts via command-line tools, WMI, or scripts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1612 - AN1612"*

Table 7187. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0587#AN1612

Analytic 1261 - AN1261

Detection of container image build activity directly on the host using Docker or Kubernetes APIs. Defenders may observe Docker build requests, anomalous Dockerfile instructions (such as downloading code from unknown IPs), or creation of new images followed by immediate deployment. This behavior chain typically consists of an unexpected image creation event correlated with outbound network communication to non-standard or untrusted destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1261 - AN1261"*

Table 7188. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0459#AN1261

Analytic 1217 - AN1217

Detects binary movement or copying between untrusted and trusted paths (e.g., /tmp/ → /usr/bin/ or /etc/init.d/) that may indicate persistence attempts or cleanup of origin traces.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1217 - AN1217"*

Table 7189. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0439#AN1217

Analytic 1172 - AN1172

Detects file movement or outbound TFTP/FTP transfers from ESXi host initiated via shell commands or injected scripts, particularly from scratch partitions or /tmp.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1172 - AN1172"*

Table 7190. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0416#AN1172

Analytic 1271 - AN1271

Anomalous creation or mounting of hidden partitions or virtual file systems. Defender view: detection of registry modifications linked to non-standard file systems, suspicious disk I/O patterns, or bootkit-like behavior where hidden volumes are accessed outside normal file system APIs.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1271 - AN1271"*

Table 7191. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0461#AN1271

Analytic 1127 - AN1127

Unusual enumeration of services and resources through cloud APIs such as AWS CLI `describe-*`, Azure Resource Manager queries, or GCP project listings. Defender perspective includes anomalous API calls, unexpected volume of service enumeration, and correlation of discovery with recently compromised sessions.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1127 - AN1127"*

Table 7192. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0402#AN1127

Analytic 1721 - AN1721

Application vetting services could look for known software packers or artifacts of packing techniques. Packing is not a definitive indicator of malicious activity, because as legitimate software may use packing techniques to reduce binary size or to protect proprietary code.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1721 - AN1721"*

Table 7193. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0644#AN1721

Analytic 1712 - AN1712

Mobile security products can detect which applications can request device administrator

permissions. Application vetting services could be extra scrutinous of applications that request device administrator permissions. The user can view applications with administrator access through the device settings, and may also notice if user data is inexplicably missing.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1712 - AN1712"*

Table 7194. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0638#AN1712

Analytic 1281 - AN1281

File access to NetworkManager connection configs and attempts to read PSK credentials from `/etc/NetworkManager/system-connections/*`.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1281 - AN1281"*

Table 7195. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0464#AN1281

Analytic 1182 - AN1182

Process execution that probes user activity artifacts (e.g., desktop files, registry history) following recent user login/unlock events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1182 - AN1182"*

Table 7196. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0420#AN1182

Analytic 1218 - AN1218

Detects movement of binaries to `~/Library/`, `/System/`, or app bundle locations, especially after initial execution or download from Safari or Mail.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1218 - AN1218"*

Table 7197. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0439#AN1218

Analytic 1128 - AN1128

Enumeration of directories, applications, or service principals through APIs such as Microsoft Graph or Okta API. Defender perspective includes unexpected listing of users, roles, applications, and abnormal access to identity management endpoints.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1128 - AN1128"*

Table 7198. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0402#AN1128

Analytic 1821 - AN1821

Google sends a notification to the device when Android Device Manager is used to locate it. Additionally, Google provides the ability for users to view their general account activity and alerts users when their credentials have been used on a new device. Apple iCloud also provides notifications to users of account activity such as when credentials have been used.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1821 - AN1821"*

Table 7199. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0702#AN1821

Analytic 1812 - AN1812

Application vetting services can look for applications requesting the permissions granting access to accessibility services or application overlay. The user can view a list of device administrators and applications that have registered Accessibility services in device settings. Applications that register an Accessibility service should be scrutinized further for malicious behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1812 - AN1812"*

Table 7200. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0697#AN1812

Analytic 1291 - AN1291

Detects rogue DHCP activity by monitoring syslog for dhclient messages assigning unauthorized DNS/gateway values. Packet capture or IDS can detect multiple competing DHCP OFFERs from non-authorized servers.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1291 - AN1291"*

Table 7201. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0468#AN1291

Analytic 1129 - AN1129

Discovery of SaaS services connected to productivity platforms (e.g., Microsoft 365, Google Workspace). Defender perspective includes unexpected enumeration of enabled services, API integrations, or OAuth applications tied to user accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1129 - AN1129"*

Table 7202. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0402#AN1129

Analytic 1219 - AN1219

Detects firmware or script relocation attempts (e.g., CLI-based `copy`, `move`, or `rename`) between temporary partitions and config startup folders on routers or switches.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1219 - AN1219"*

Table 7203. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0439#AN1219

Analytic 1192 - AN1192

Detects guest VMs or management agents issuing HTTP(S) traffic to external services without a valid patch management or backup justification.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1192 - AN1192"*

Table 7204. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0425#AN1192

Analytic 1331 - AN1331

Identify repeated DNS resolutions where the same domain name returns multiple IPs in short succession, combined with low TTL values and high query volume from unusual processes. Correlate with process lineage (e.g., Office apps spawning abnormal DNS lookups).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1331 - AN1331"*

Table 7205. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0485#AN1331

Analytic 1313 - AN1313

Adversaries using WinRM to remotely execute commands, launch child processes, or access WMI. The detection chain includes service use, network activity, remote session logon, and process creation within a short temporal window.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1313 - AN1313"*

Table 7206. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0477#AN1313

Analytic 1133 - AN1133

Monitor Windows Registry modifications to Winlogon keys (Shell, Userinit, Notify) that introduce new executable or DLL paths. Correlate these changes with subsequent DLL loading, image loads, or process creation originating from winlogon.exe or userinit.exe. Abnormal child process lineage or unauthorized binaries in C:\Windows\System32 may indicate abuse.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1133 - AN1133"*

Table 7207. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0404#AN1133

Analytic 1143 - AN1143

Cloud-hosted VM or container generates spoofed UDP requests to third-party services on known amplifier ports, with high outbound-to-inbound traffic ratios in VPC Flow Logs

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1143 - AN1143"*

Table 7208. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0408#AN1143

Analytic 1134 - AN1134

Correlates LNK file execution with embedded resource extraction or suspicious network activity following initial launch, often leading to payload delivery via disguised icons.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1134 - AN1134"*

Table 7209. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0405#AN1134

Analytic 1431 - AN1431

Detects use of 'esxcli system' or direct interpreter commands (e.g., busybox shell) invoked from SSH or host terminal unexpectedly.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1431 - AN1431"*

Table 7210. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0516#AN1431

Analytic 1413 - AN1413

Detects non-browser processes that establish encrypted outbound connections (e.g., TLS/SSL) to unfamiliar or atypical destinations for the host/user, following a data staging or compression event.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1413 - AN1413"*

Table 7211. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0512#AN1413

Analytic 1341 - AN1341

Repeated failed authentication attempts to container APIs, control planes, or login shells across many user names using same password

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1341 - AN1341"*

Table 7212. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0487#AN1341

Analytic 1314 - AN1314

Cause→effect chain: (1) User-facing app (Office/PDF/archiver/browser) records an open/click or abnormal event, then (2) a downloaded file is created in a user-writable path and/or decompressed, (3) the parent user app spawns a living-off-the-land binary (e.g., powershell/cmd/mshta/rundll32/msiexec/wscript/expand/zip) or installer, and (4) immediate outbound HTTP(S)/DNS/SMB from the same lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1314 - AN1314"*

Table 7213. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0478#AN1314

Analytic 1531 - AN1531

Detection of non-interactive or suspicious processes accessing Bluetooth interfaces and transmitting outbound traffic following file access or staging activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1531 - AN1531"*

Table 7214. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0554#AN1531

Analytic 1351 - AN1351

A process explicitly forges its parent using EXTENDED_STARTUPINFO + PROC_THREAD_ATTRIBUTE_PARENT_PROCESS (UpdateProcThreadAttribute → CreateProcess[A/W]/CreateProcessAsUserW) or other Native API paths, resulting in **mismatched/implausible lineage** across ETW EventHeader ProcessId, Security 4688 Creator Process ID/Name, and sysmon ParentProcessGuid. Often paired with privilege escalation when the chosen parent runs as SYSTEM.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1351 - AN1351"*

Table 7215. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0489#AN1351

Analytic 1315 - AN1315

Cause→effect chain: (1) User app/browser/archiver logs an open/click or abnormal exit, (2) new executable/script/archive extracted into $HOME/Downloads, /tmp, or ~/.cache, (3) parent app spawns shell/interpreter (bash/sh/python/node/curl/wget) or desktop file, and (4) new outbound

connection(s) from the child lineage.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1315 - AN1315"*

Table 7216. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0478#AN1315

Analytic 1513 - AN1513

Office apps or scripts writing files followed by xattr manipulation (to evade quarantine) and subsequent HTTPS uploads. Defender perspective: anomalous file modification + outbound TLS traffic originating from non-networking apps (Word, Excel, Preview).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1513 - AN1513"*

Table 7217. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0548#AN1513

Analytic 1153 - AN1153

Unusual access to bash history, registry credentials paths, or private key files by unauthorized or scripting tools, with correlated file and process activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1153 - AN1153"*

Table 7218. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0412#AN1153

Analytic 1135 - AN1135

Abuse of extended attributes (xattrs) to embed hidden payloads into legitimate files. Defender perspective: detect anomalous use of setfattr or getfattr commands, or direct syscalls (setxattr, getxattr) where attributes are unusually large or contain encoded data. Behavior chain includes: (1) execution of setfattr with suspicious namespaces (user., trusted.), (2) file metadata modification inconsistent with file size/hash, and (3) subsequent process execution reading attributes followed by decoding activity.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1135 - AN1135"*

Table 7219. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0406#AN1135

Analytic 1316 - AN1316

Cause→effect chain: (1) unified logs show application open/click or crash for Safari/Chrome/Office/Preview/archiver, (2) file write/extraction into ~/Downloads, /private/var/folders/* or ~/Library, (3) parent app spawns osascript/bash/zsh/curl/python or opens a quarantined app with Gatekeeper prompts, (4) network egress from child.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1316 - AN1316"*

Table 7220. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0478#AN1316

Analytic 1613 - AN1613

Enumeration of users and groups through suspicious shell commands or unauthorized access to /etc/passwd or /etc/shadow.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1613 - AN1613"*

Table 7221. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0587#AN1613

Analytic 1631 - AN1631

Monitoring adversary access to sensitive process memory via the /proc filesystem to extract credential material, often involving multi-step access to /proc/[pid]/mem or /proc/[pid]/maps combined with privilege escalation or credential scraping binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1631 - AN1631"*

Table 7222. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0593#AN1631

Analytic 1163 - AN1163

Access of mounted cloud shares or document repositories via browser, terminal, or Finder by users not typically interacting with those resources. Includes script-based enumeration or mass download.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1163 - AN1163"*

Table 7223. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0413#AN1163

Analytic 1361 - AN1361

Monitor for anomalous access to financial applications, browser-based banking sessions, or enterprise ERP systems from Windows endpoints. Detect mass emailing of payment instructions, sudden rule changes in Outlook for financial staff, or use of clipboard data exfiltration tied to cryptocurrency wallet addresses.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1361 - AN1361"*

Table 7224. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0495#AN1361

Analytic 1136 - AN1136

Abuse of extended attributes (xattrs) to hide payloads in com.apple.* or custom keys. Defender perspective: monitor suspicious use of xattr command with -w (write) and -p (print) flags, especially when followed by execution of interpreters like bash, Python, or osascript. Behavior chain includes: (1) suspicious file modification with new com.apple.* attributes, (2) attribute content inconsistent with expected metadata tags (e.g., high entropy), (3) subsequent process execution correlated with extraction of the attribute.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1136 - AN1136"*

Table 7225. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0406#AN1136

Analytic 1317 - AN1317

Cause→effect chain in CI/dev desktops: (1) user triggers container run/pull after opening a doc/link/script, (2) newly created image/container uses unexpected external registry or entrypoint, (3) container starts and immediately egresses to suspicious destinations.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1317 - AN1317"*

Table 7226. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0478#AN1317

Analytic 1137 - AN1137

Detects anomalous usage of local accounts to log into a system, especially accounts not typically used interactively or outside business hours.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1137 - AN1137"*

Table 7227. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0407#AN1137

Analytic 1173 - AN1173

Detects internal hosts generating large outbound FTP/TFTP/SMB sessions to external IPs, or file transfers using non-standard ports and application mismatches (e.g., FTP over port 80).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1173 - AN1173"*

Table 7228. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0416#AN1173

Analytic 1371 - AN1371

Detection of adversary disabling endpoint security tools by unloading launch agents/daemons, modifying configuration profiles, or using security/uninstall commands to remove agents.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1371 - AN1371"*

Table 7229. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0497#AN1371

Analytic 1713 - AN1713

Unexpected loss of radio signal could indicate that a device is being actively jammed.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1713 - AN1713"*

Table 7230. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0639#AN1713

Analytic 1731 - AN1731

Since data encryption is a common practice in many legitimate applications and uses standard programming language-specific APIs, encrypting data for command and control communication is regarded as undetectable to the user.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1731 - AN1731"*

Table 7231. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0650#AN1731

Analytic 1183 - AN1183

Access to shell history or GUI input state (xdotool, xinput) for presence validation prior to payload execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1183 - AN1183"*

Table 7232. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0420#AN1183

Analytic 1138 - AN1138

Detects interactive or service logins from local accounts outside expected operational context or at anomalous times.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1138 - AN1138"*

Table 7233. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0407#AN1138

Analytic 1381 - AN1381

Detects compilation activity using csc.exe, ilasm.exe, or msbuild.exe initiated by user-space processes outside typical development environments, followed by execution or network activity from newly written binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1381 - AN1381"*

Table 7234. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0501#AN1381

Analytic 1318 - AN1318

Cause→effect chain in cloud consoles: (1) user clicks link then invokes instance/image creation via API, (2) instance/image originates from external AMI or unknown image, (3) instance immediately egresses or retrieves payloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1318 - AN1318"*

Table 7235. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0478#AN1318

Analytic 1831 - AN1831

Application vetting services could look for usage of the `READ_PRIVILEGED_PHONE_STATE` Android permission. This could indicate that non-system apps are attempting to access information that they do not have access to.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1831 - AN1831"*

Table 7236. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0708#AN1831

Analytic 1813 - AN1813

[Exfiltration Over Alternative Protocol](https://attack.mitre.org/techniques/T1639)s can be difficult to detect, and therefore enterprises may be better served focusing on detection at other stages of adversarial behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1813 - AN1813"*

Table 7237. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0698#AN1813

Analytic 1193 - AN1193

Processes accessing raw logical drives (e.g., \.\C:) to bypass file system protections or directly manipulate data structures.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1193 - AN1193"*

Table 7238. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0426#AN1193

Analytic 1319 - AN1319

Modification of COR_PROFILER-related environment variables or Registry keys (COR_ENABLE_PROFILING, COR_PROFILER, COR_PROFILER_PATH), combined with anomalous .NET process creation or unmanaged DLL loads. Defender observes registry modifications, suspicious process creation with altered environment variables, and profiler DLLs loaded unexpectedly into .NET CLR processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1319 - AN1319"*

Table 7239. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0479#AN1319

Analytic 1391 - AN1391

Detects symmetric key-based encryption operations (e.g., AES via Python, AppleScript, or OpenSSL) followed by unusual outbound connections from non-browser applications or scripted tools.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1391 - AN1391"*

Table 7240. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0503#AN1391

Analytic 1139 - AN1139

Detects abnormal or rare logins via local accounts through system or remote mechanisms such as SSH.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1139 - AN1139"*

Table 7241. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0407#AN1139

Analytic 1414 - AN1414

Detects staged file access (e.g., archive or obfuscation), followed by an encrypted outbound connection (TLS/HTTPS) from unusual processes such as curl/wget, Python scripts, or custom

binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1414 - AN1414"*

Table 7242. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0512#AN1414

Analytic 1441 - AN1441

Detects GUI-based credential prompts invoked via zenity/kdialog/dialog or X11 APIs from non-user-facing scripts or background shell sessions, often with authentication-related text.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1441 - AN1441"*

Table 7243. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0521#AN1441

Analytic 1144 - AN1144

Detects anomalous NTLM LogonType 3 authentications that occur without accompanying domain logon events, especially from lateral systems or involving built-in administrative tools. Monitors for mismatches between source user context and system being accessed. Correlates LogonSession creation, NTLM authentications, and process/service initiation to identify suspicious use of stolen password hashes for remote access or service logon without password entry. Detects overpass-the-hash by combining Kerberos ticket issuance with NTLM-based lateral movement.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1144 - AN1144"*

Table 7244. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0409#AN1144

Analytic 1514 - AN1514

Abnormal API calls from user accounts invoking file upload endpoints outside normal baselines (M365, Google Drive, Box). Defender perspective: monitor unified audit logs for elevated frequency of Upload, Create, or Copy operations from compromised accounts.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1514 - AN1514"*

Table 7245. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0548#AN1514

Analytic 1154 - AN1154

Reading of sensitive files like .bash_history, /etc/shadow, or private key directories by unauthorized users or unusual processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1154 - AN1154"*

Table 7246. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0412#AN1154

Analytic 1415 - AN1415

Detects abnormal encrypted network connections (via TLS/HTTPS) initiated by non-browser binaries, particularly after sensitive file access or compression events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1415 - AN1415"*

Table 7247. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0512#AN1415

Analytic 1145 - AN1145

Monitoring of file access to network shares (e.g., C$, Admin$) followed by unusual read or copy operations by processes not typically associated with such activity (e.g., PowerShell, certutil).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1145 - AN1145"*

Table 7248. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0410#AN1145

Analytic 1451 - AN1451

Crafted ‘synful knock’ patterns toward routers/switches (same src hits interface/broadcast/network address on same port in short order) followed by ACL/telnet/SSH enablement or module change. Detect device image/ACL updates then a new mgmt session.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1451 - AN1451"*

Table 7249. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0524#AN1451

Analytic 1541 - AN1541

Detect commands such as 'esxcli system shutdown' or 'vim-cmd vmsvc/power.shutdown' executed outside of maintenance windows or via unusual users. Reboot logs in hostd.log and shell logs should be correlated.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1541 - AN1541"*

Table 7250. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0559#AN1541

Analytic 1641 - AN1641

Detection of suspicious access to password manager processes (KeePass, 1Password, LastPass, Bitwarden) through abnormal process injection, memory reads, or command-line usage of vault-related DLLs. Correlates process creation with OS API calls and file access to vault databases (.kdbx, .opvault, .ldb).

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1641 - AN1641"*

Table 7251. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0597#AN1641

Analytic 1416 - AN1416

Detects unexpected encrypted outbound connections from management components or guest VMs using TLS, particularly after data volume spikes or script-based orchestration from within guest environments.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1416 - AN1416"*

Table 7252. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0512#AN1416

Analytic 1614 - AN1614

Detection of user account enumeration through tools like dscl, dscacheutil, or loginshell enumeration via command-line.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1614 - AN1614"*

Table 7253. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0587#AN1614

Analytic 1146 - AN1146

Unusual access or copying of files from mounted network drives (e.g., NFS, CIFS/SMB) by user shells or scripts followed by large data transfer.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1146 - AN1146"*

Table 7254. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0410#AN1146

Analytic 1164 - AN1164

Detects AppleScript execution via 'osascript', NSAppleScript/OSAScript APIs, and abnormal application control events across user sessions. Focuses on causal chains such as osascript spawning child processes, script-induced keystrokes, or API-backed dialog spoofing.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1164 - AN1164"*

Table 7255. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0414#AN1164

Analytic 1461 - AN1461

Execution of files containing right-to-left override characters (U+202E) to masquerade true file extensions. Often found in phishing payloads or file downloads.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1461 - AN1461"*

Table 7256. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0527#AN1461

Analytic 1417 - AN1417

Detects adversary behavior accessing Windows cached domain credential files using tools like Mimikatz, reg.exe, or PowerShell, often combined with registry exports or LSASS memory scraping.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1417 - AN1417"*

Table 7257. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0513#AN1417

Analytic 1174 - AN1174

Monitor command execution of powercfg.exe with arguments modifying sleep, hibernate, or display timeouts. Abnormal or repeated modifications to power settings outside administrative baselines may indicate persistence attempts. Correlate process creation with registry and system configuration changes to build behavioral chains.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1174 - AN1174"*

Table 7258. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0417#AN1174

Analytic 1147 - AN1147

Detection of file access from mounted SMB shares followed by copy or exfil commands from Terminal or script interpreter processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1147 - AN1147"*

Table 7259. Table References

https://attack.mitre.org/detectionstrategies/DET0419#AN1179

Analytic 1971 - AN1971

If infrastructure or patterns in malware, tooling, certificates, or malicious web content have been previously identified, internet scanning may uncover when an adversary has staged their capabilities. Much of this activity will take place outside the visibility of the target organization, making detection of this behavior difficult. Detection efforts may be focused on related stages of the adversary lifecycle, such as initial access and post-compromise behaviors.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1971 - AN1971"*

Table 7328. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0839#AN1971

Analytic 1197 - AN1197

Detects the modification or addition of Launch Agents or Startup Items to establish persistence. Adversaries may write plist or executable files to ~/Library/LaunchAgents/, /Library/StartupItems/, or similar directories and configure them to run at user or system boot. Detection requires correlating file creation or modification events with subsequent user logon or boot-time process execution.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1197 - AN1197"*

Table 7329. Table References

Analytic 1199 - AN1199

Detects access to known password store files (e.g., /etc/shadow, GNOME Keyring, KWallet, browser credential databases). Monitors anomalous process read attempts and suspicious API calls that attempt to extract stored credentials.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1199 - AN1199"*

Table 7339. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0430#AN1199

Analytic 1222 - AN1222

Detection of anomalous registry modifications to Subject Interface Packages (SIPs) or trust provider DLL mappings, unexpected loading of non-Microsoft cryptographic modules, or attempts to redirect WinVerifyTrust validation logic. Defender view focuses on registry tampering, suspicious DLL loads into trusted processes, and abnormal trust validation failures correlated across event streams.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1222 - AN1222"*

Table 7340. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0442#AN1222

Analytic 1322 - AN1322

Detects unauthorized changes to locally hosted login pages on macOS (common in developer VPN environments) and links file edits to cron jobs, background scripts, or SUID binaries.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1322 - AN1322"*

Table 7341. Table References

Links

https://attack.mitre.org/detectionstrategies/DET0480#AN1322

Analytic 1223 - AN1223

Detects anomalous process execution patterns where a process's parent terminates quickly after process creation or is re-parented to 'init' (PID 1), often indicating double-fork or daemon-style detachment. These behaviors sever the parent-child relationship and obscure the execution origin in process tree analysis.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1223 - AN1223"*

Table 7342. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0443#AN1223

Analytic 1232 - AN1232

Direct use of `nc`, `socat`, or reverse tunnel scripts initiated by abnormal user contexts or unauthorized VIBs initiating connections from hypervisor to external systems.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1232 - AN1232"*

Table 7343. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0445#AN1232

Analytic 1224 - AN1224

Detects execution patterns where a child process is detached from its original parent, often showing up under 'launchd' (PID 1) with no parent lineage. These breakages in the process tree are indicative of evasive techniques using `daemon()`, `fork()` or background execution flags.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1224 - AN1224"*

Table 7344. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0443#AN1224

Analytic 1422 - AN1422

Detects container breakout behavior via exploitation (e.g., DirtyPipe, CVE-2022-0847), followed by host OS interaction or escalated capability assignment.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1422 - AN1422"*

Table 7345. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0514#AN1422

Analytic 1242 - AN1242

Detection focuses on abnormal or unauthorized cloud instance creation events. From a defender's perspective, suspicious behavior includes VM/instance creation by rarely used or newly created accounts, creation events from unusual geolocations, or rapid sequences of snapshot creation followed by instance creation and mounting. Unexpected network or IAM policy changes applied to new instances can indicate adversarial use rather than legitimate provisioning.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1242 - AN1242"*

Table 7346. Table References

Analytic 1852 - AN1852

Dynamic analysis, when used in application vetting, may in some cases be able to identify malicious code in obfuscated or encrypted form by detecting the code at execution time (after it is deobfuscated or decrypted). Some application vetting techniques apply reputation analysis of the application developer and can alert to potentially suspicious applications without actual examination of application code.

https://attack.mitre.org/detectionstrategies/DET0495#AN1363

Analytic 1633 - AN1633

Detects exploitation attempts targeting defensive security software or OS services. Defender observation includes abnormal process behavior (e.g., AV or EDR crashing unexpectedly), unsigned/untrusted modules loaded into defensive processes, or privilege escalation from security agent services. Multi-event correlation ties exploitation attempts to subsequent evasive behavior like service termination or missing logs.

Analytic 1346 - AN1346

Behavioral chain: (1) third-party interactive login or mobileconfig-based device enrollment; (2) privilege use or admin group change; (3) lateral movement mounts/ssh. Correlate unified logs and network telemetry.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1346 - AN1346"*

Table 7525. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0488#AN1346

Analytic 1436 - AN1436

Adversaries inject VBA macros into Office templates such as Normal.dotm or Personal.xlsb or redirect Office template load path via registry key (GlobalDotName) to gain persistence. Template macros trigger execution of malicious code on application startup.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1436 - AN1436"*

Table 7526. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0519#AN1436

Analytic 1643 - AN1643

Detection of password manager database access (1Password .opvault, LastPass caches, KeePass .kdbx) outside expected parent processes. Identifies memory scraping attempts via suspicious API calls or tools attaching to password manager processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1643 - AN1643"*

Table 7527. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0597#AN1643

Analytic 1634 - AN1634

Detects kernel- or user-space exploitation attempts targeting auditd, AV daemons, or security monitoring agents. Defender observation includes unexpected segfaults, privilege escalation

attempts from low-privileged processes, or modifications to security binaries. Correlates exploitation attempts with subsequent gaps in logging or terminated processes.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1634 - AN1634"*

Table 7528. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0595#AN1634

Analytic 1473 - AN1473

Detects anomalous CI/CD workflow execution originating from forked repositories, with pull request (PR) metadata or commit messages containing suspicious patterns (e.g., encoded payloads), coupled with the use of insecure pipeline triggers like `pull_request_target` or excessive API usage of CI/CD secrets. Correlation with unusual artifact generation or secret exfiltration via encoded or external network destination URLs confirms suspicious behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1473 - AN1473"*

Table 7529. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0533#AN1473

Analytic 1437 - AN1437

Malicious VBA macros embedded in base templates like Normal.dotm or Personal.xlsb are automatically loaded and executed at startup. Template path may be hijacked to load a remote or attacker-controlled template via GlobalDotName registry setting.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1437 - AN1437"*

Table 7530. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0519#AN1437

Analytic 1374 - AN1374

Detection of adversaries modifying startup configuration files to disable signature verification, logging, or monitoring features.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1374 - AN1374"*

Table 7531. Table References

Links
https://attack.mitre.org/detectionstrategies/DET0497#AN1374

Analytic 1347 - AN1347

Behavioral chain: (1) delegated admin or external identity establishes session (e.g., partner/reseller DAP, B2B guest, SAML/OAuth trust); (2) role elevation or app consent/permission grant; (3) downstream privileged actions in the tenant. Correlate IdP sign-in, admin/role assignment, and consent/admin-on-behalf events.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1347 - AN1347"*

Table 7532. Table References

Analytic 1743 - AN1743

When vetting applications for potential security weaknesses, the vetting process could look for insecure use of Intents. Developers should be encouraged to use techniques to ensure that the intent can only be sent to an appropriate destination (e.g., use explicit rather than implicit intents, permission checking, checking of the destination app's signing certificate, or utilizing the App Links feature). For mobile applications using OAuth, encourage use of best practice.(Citation: IETF-OAuthNativeApps)(Citation: Android-AppLinks) On Android, users may be presented with a popup to select the appropriate application to open a URI in. If the user sees an application they do not recognize, they can remove it.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1743 - AN1743"*

Analytic 1644 - AN1644

Application vetting services may detect API calls to `performGlobalAction(int)`. The user can view a list of device administrators and applications that have registered accessibility services in device settings. The user can typically visually see when an action happens that they did not initiate and can subsequently review installed applications for any out of place or unknown ones. Applications that register an accessibility service or request device administrator permissions should be scrutinized further for malicious behavior.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1644 - AN1644"*

Table 7621. Table References

Analytic 1744 - AN1744

When vetting applications for potential security weaknesses, the vetting process could look for insecure use of Intents. Developers should be encouraged to use techniques to ensure that the intent can only be sent to an appropriate destination (e.g., use explicit rather than implicit intents, permission checking, checking of the destination app's signing certificate, or utilizing the App Links feature). For mobile applications using OAuth, encourage use of best practice.(Citation: IETF-OAuthNativeApps)(Citation: Android-AppLinks) On Android, users may be presented with a popup to select the appropriate application to open a URI in. If the user sees an application they do not recognize, they can remove it.

The tag is: *misp-galaxy:x-mitre-analytic="Analytic 1744 - AN1744"*

Analytic 1694 - AN1694

When vetting applications for potential security weaknesses, the vetting process could look for insecure use of Intents. Developers should be encouraged to use techniques to ensure that the intent can only be sent to an appropriate destination (e.g., use explicit rather than implicit intents, permission checking, checking of the destination app's signing certificate, or utilizing the App Links feature). For mobile applications using OAuth, encourage use of best practice. (Citation: IETF-OAuthNativeApps)(Citation: Android-AppLinks) On Android, users may be presented with a popup to select the appropriate application to open the URI in. If the user sees an application they do not recognize, they can remove it.

Analytic 1955 - AN1955

Monitor and analyze traffic patterns and packet inspection associated to protocol(s) that do not follow the expected protocol standards and traffic flows (e.g extraneous packets that do not belong to established flows, gratuitous or anomalous traffic patterns, anomalous syntax, or structure). Consider correlation with process monitoring and command line to detect anomalous processes execution and command line arguments associated to traffic patterns (e.g. monitor anomalies in use of files that do not normally initiate connections for respective protocol(s)). Depending on the specific method of phishing, the detections can vary. Monitor for suspicious email activity, such as numerous accounts receiving messages from a single unusual/unknown sender. Filtering based on DKIM+SPF or header analysis can help detect when the email sender is spoofed.(Citation: Microsoft Anti Spoofing)(Citation: ACSC Email Spoofing) When it comes to following links, monitor for references to uncategorized or known-bad sites. URL inspection within email (including expanding shortened links) can also help detect links leading to known malicious sites. Monitor social media traffic for suspicious activity, including messages requesting information as well as abnormal file or data transfers (especially those involving unknown, or otherwise suspicious accounts).

Monitor call logs from corporate devices to identify patterns of potential voice phishing, such as calls to/from known malicious phone numbers. Monitor network data for uncommon data flows. Processes utilizing the network that do not normally have network communication or have never been seen before are suspicious.

Analytic 1796 - AN1796

Application vetting services could look for `android.permission.READ_SMS` in an Android application's manifest. Most applications do not need access to SMS messages, so extra scrutiny could be applied to those that request it. On Android, the user can manage which applications have permission to access SMS messages through the device settings screen, revoking the permission if necessary.

MITRE

Search for Victim’s Publicly Available Research Materials

Adversaries may search publicly available research to learn how and where machine learning is used within a victim organization. The adversary can use this information to identify targets for attack, or to tailor an existing attack to make it more effective. Organizations often use open source model architectures trained on additional proprietary data in production. Knowledge of this underlying architecture allows the adversary to craft more realistic proxy models ([Create Proxy ML Model](/techniques/AML.T0005)). An adversary can search these resources for publications for

authors employed at the victim organization.

Research materials may exist as academic papers published in [Journals and Conference Proceedings](/techniques/AML.T0000.000), or stored in [Pre-Print Repositories](/techniques/AML.T0000.001), as well as [Technical Blogs](/techniques/AML.T0000.002).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Search for Victim's Publicly Available Research Materials"*

Table 7802. Table References

Links
https://atlas.mitre.org/techniques/AML.T0000

Journals and Conference Proceedings

Many of the publications accepted at premier machine learning conferences and journals come from commercial labs. Some journals and conferences are open access, others may require paying for access or a membership. These publications will often describe in detail all aspects of a particular approach for reproducibility. This information can be used by adversaries to implement the paper.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Journals and Conference Proceedings"*

Table 7803. Table References

Links
https://atlas.mitre.org/techniques/AML.T0000.000

Pre-Print Repositories

Pre-Print repositories, such as arXiv, contain the latest academic research papers that haven't been peer reviewed. They may contain research notes, or technical reports that aren't typically published in journals or conference proceedings. Pre-print repositories also serve as a central location to share papers that have been accepted to journals. Searching pre-print repositories provide adversaries with a relatively up-to-date view of what researchers in the victim organization are working on.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Pre-Print Repositories"*

Table 7804. Table References

Links
https://atlas.mitre.org/techniques/AML.T0000.001

Technical Blogs

Research labs at academic institutions and Company R&D divisions often have blogs that highlight

their use of machine learning and its application to the organizations unique problems. Individual researchers also frequently document their work in blogposts. An adversary may search for posts made by the target victim organization or its employees. In comparison to [Journals and Conference Proceedings](/techniques/AML.T0000.000) and [Pre-Print Repositories](/techniques/AML.T0000.001) this material will often contain more practical aspects of the machine learning system. This could include underlying technologies and frameworks used, and possibly some information about the API access and use case. This will help the adversary better understand how that organization is using machine learning internally and the details of their approach that could aid in tailoring an attack.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Technical Blogs"*

Table 7805. Table References

Links
https://atlas.mitre.org/techniques/AML.T0000.002

Search for Publicly Available Adversarial Vulnerability Analysis

Much like the [Search for Victim's Publicly Available Research Materials](/techniques/AML.T0000), there is often ample research available on the vulnerabilities of common models. Once a target has been identified, an adversary will likely try to identify any pre-existing work that has been done for this class of models. This will include not only reading academic papers that may identify the particulars of a successful attack, but also identifying pre-existing implementations of those attacks. The adversary may obtain [Adversarial ML Attack Implementations](/techniques/AML.T0016.000) or develop their own [Adversarial ML Attacks](/techniques/AML.T0017.000) if necessary.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Search for Publicly Available Adversarial Vulnerability Analysis"*

Table 7806. Table References

Links
https://atlas.mitre.org/techniques/AML.T0001

Acquire Public ML Artifacts

Adversaries may search public sources, including cloud storage, public-facing services, and software or data repositories, to identify machine learning artifacts. These machine learning artifacts may include the software stack used to train and deploy models, training and testing data, model configurations and parameters. An adversary will be particularly interested in artifacts hosted by or associated with the victim organization as they may represent what that organization uses in a production environment. Adversaries may identify artifact repositories via other resources associated with the victim organization (e.g. [Search Victim-Owned Websites](/techniques/AML.T0003) or [Search for Victim's Publicly Available Research Materials](/techniques/AML.T0000)). These ML artifacts often provide adversaries with details of

the ML task and approach.

ML artifacts can aid in an adversary's ability to [Create Proxy ML Model](/techniques/AML.T0005). If these artifacts include pieces of the actual model in production, they can be used to directly [Craft Adversarial Data](/techniques/AML.T0043). Acquiring some artifacts requires registration (providing user details such email/name), AWS keys, or written requests, and may require the adversary to [Establish Accounts](/techniques/AML.T0021).

Artifacts might be hosted on victim-controlled infrastructure, providing the victim with some information on who has accessed that data.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Acquire Public ML Artifacts"*

Table 7807. Table References

Links
https://atlas.mitre.org/techniques/AML.T0002

Datasets

Adversaries may collect public datasets to use in their operations. Datasets used by the victim organization or datasets that are representative of the data used by the victim organization may be valuable to adversaries. Datasets can be stored in cloud storage, or on victim-owned websites. Some datasets require the adversary to [Establish Accounts](/techniques/AML.T0021) for access.

Acquired datasets help the adversary advance their operations, stage attacks, and tailor attacks to the victim organization.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Datasets"*

Table 7808. Table References

Links
https://atlas.mitre.org/techniques/AML.T0002.000

Models

Adversaries may acquire public models to use in their operations. Adversaries may seek models used by the victim organization or models that are representative of those used by the victim organization. Representative models may include model architectures, or pre-trained models which define the architecture as well as model parameters from training on a dataset. The adversary may search public sources for common model architecture configuration file formats such as YAML or Python configuration files, and common model storage file formats such as ONNX (.onnx), HDF5 (.h5), Pickle (.pkl), PyTorch (.pth), or TensorFlow (.pb, .tflite).

Acquired models are useful in advancing the adversary's operations and are frequently used to tailor attacks to the victim model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Models"*

Table 7809. Table References

Links
https://atlas.mitre.org/techniques/AML.T0002.001

Search Victim-Owned Websites

Adversaries may search websites owned by the victim for information that can be used during targeting. Victim-owned websites may contain technical details about their ML-enabled products or services. Victim-owned websites may contain a variety of details, including names of departments/divisions, physical locations, and data about key employees such as names, roles, and contact info. These sites may also have details highlighting business operations and relationships.

Adversaries may search victim-owned websites to gather actionable information. This information may help adversaries tailor their attacks (e.g. [Adversarial ML Attacks](/techniques/AML.T0017.000) or [Manual Modification](/techniques/AML.T0043.003)). Information from these sources may reveal opportunities for other forms of reconnaissance (e.g. [Search for Victim's Publicly Available Research Materials](/techniques/AML.T0000) or [Search for Publicly Available Adversarial Vulnerability Analysis](/techniques/AML.T0001))

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Search Victim-Owned Websites"*

Table 7810. Table References

Links
https://atlas.mitre.org/techniques/AML.T0003

Search Application Repositories

Adversaries may search open application repositories during targeting. Examples of these include Google Play, the iOS App store, the macOS App Store, and the Microsoft Store.

Adversaries may craft search queries seeking applications that contain a ML-enabled components. Frequently, the next step is to [Acquire Public ML Artifacts](/techniques/AML.T0002).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Search Application Repositories"*

Table 7811. Table References

Links
https://atlas.mitre.org/techniques/AML.T0004

Create Proxy ML Model

Adversaries may obtain models to serve as proxies for the target model in use at the victim organization. Proxy models are used to simulate complete access to the target model in a fully offline manner.

Adversaries may train models from representative datasets, attempt to replicate models from victim inference APIs, or use available pre-trained models.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Create Proxy ML Model"*

Table 7812. Table References

Links
https://atlas.mitre.org/techniques/AML.T0005

Train Proxy via Gathered ML Artifacts

Proxy models may be trained from ML artifacts (such as data, model architectures, and pre-trained models) that are representative of the target model gathered by the adversary. This can be used to develop attacks that require higher levels of access than the adversary has available or as a means to validate pre-existing attacks without interacting with the target model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Train Proxy via Gathered ML Artifacts"*

Table 7813. Table References

Links
https://atlas.mitre.org/techniques/AML.T0005.000

Train Proxy via Replication

Adversaries may replicate a private model. By repeatedly querying the victim's [AI Model Inference API Access](/techniques/AML.T0040), the adversary can collect the target model's inferences into a dataset. The inferences are used as labels for training a separate model offline that will mimic the behavior and performance of the target model.

A replicated model that closely mimic's the target model is a valuable resource in staging the attack. The adversary can use the replicated model to [Craft Adversarial Data](/techniques/AML.T0043) for various purposes (e.g. [Evade ML Model](/techniques/AML.T0015), [Spamming ML System with Chaff Data](/techniques/AML.T0046)).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Train Proxy via Replication"*

Table 7814. Table References

Links
https://atlas.mitre.org/techniques/AML.T0005.001

Use Pre-Trained Model

Adversaries may use an off-the-shelf pre-trained model as a proxy for the victim model to aid in staging the attack.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Use Pre-Trained Model"*

Table 7815. Table References

Links
https://atlas.mitre.org/techniques/AML.T0005.002

Active Scanning

An adversary may probe or scan the victim system to gather information for targeting. This is distinct from other reconnaissance techniques that do not involve direct interaction with the victim system.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Active Scanning"*

Table 7816. Table References

Links
https://atlas.mitre.org/techniques/AML.T0006

Discover ML Artifacts

Adversaries may search private sources to identify machine learning artifacts that exist on the system and gather information about them. These artifacts can include the software stack used to train and deploy models, training and testing data management systems, container registries, software repositories, and model zoos.

This information can be used to identify targets for further collection, exfiltration, or disruption, and to tailor and improve attacks.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Discover ML Artifacts"*

Table 7817. Table References

Links
https://atlas.mitre.org/techniques/AML.T0007

Acquire Infrastructure

Adversaries may buy, lease, or rent infrastructure for use throughout their operation. A wide variety of infrastructure exists for hosting and orchestrating adversary operations. Infrastructure solutions include physical or cloud servers, domains, mobile devices, and third-party web services. Free resources may also be used, but they are typically limited. Infrastructure can also include physical components such as countermeasures that degrade or disrupt AI components or sensors, including printed materials, wearables, or disguises.

Use of these infrastructure solutions allows an adversary to stage, launch, and execute an operation. Solutions may help adversary operations blend in with traffic that is seen as normal, such as contact to third-party web services. Depending on the implementation, adversaries may use infrastructure that makes it difficult to physically tie back to them as well as utilize infrastructure

that can be rapidly provisioned, modified, and shut down.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Acquire Infrastructure"*

Table 7818. Table References

Links
https://atlas.mitre.org/techniques/AML.T0008

ML Development Workspaces

Developing and staging machine learning attacks often requires expensive compute resources. Adversaries may need access to one or many GPUs in order to develop an attack. They may try to anonymously use free resources such as Google Colaboratory, or cloud resources such as AWS, Azure, or Google Cloud as an efficient way to stand up temporary resources to conduct operations. Multiple workspaces may be used to avoid detection.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML Development Workspaces"*

Table 7819. Table References

Links
https://atlas.mitre.org/techniques/AML.T0008.000

Consumer Hardware

Adversaries may acquire consumer hardware to conduct their attacks. Owning the hardware provides the adversary with complete control of the environment. These devices can be hard to trace.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Consumer Hardware"*

Table 7820. Table References

Links
https://atlas.mitre.org/techniques/AML.T0008.001

Domains

Adversaries may acquire domains that can be used during targeting. Domain names are the human readable names used to represent one or more IP addresses. They can be purchased or, in some cases, acquired for free.

Adversaries may use acquired domains for a variety of purposes (see [ATT&CK](https://attack.mitre.org/techniques/T1583/001/)). Large AI datasets are often distributed as a list of URLs to individual datapoints. Adversaries may acquire expired domains that are included in these datasets and replace individual datapoints with poisoned examples ([Publish Poisoned Datasets](/techniques/AML.T0019)).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Domains"*

Table 7821. Table References

Links
https://atlas.mitre.org/techniques/AML.T0008.002

Physical Countermeasures

Adversaries may acquire or manufacture physical countermeasures to aid or support their attack.

These components may be used to disrupt or degrade the model, such as adversarial patterns printed on stickers or T-shirts, disguises, or decoys. They may also be used to disrupt or degrade the sensors used in capturing data, such as laser pointers, light bulbs, or other tools.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Physical Countermeasures"*

Table 7822. Table References

Links
https://atlas.mitre.org/techniques/AML.T0008.003

ML Supply Chain Compromise

Adversaries may gain initial access to a system by compromising the unique portions of the ML supply chain. This could include [Hardware](/techniques/AML.T0010.000), [Data](/techniques/AML.T0010.002) and its annotations, parts of the ML [ML Software](/techniques/AML.T0010.001) stack, or the [Model](/techniques/AML.T0010.003) itself. In some instances the attacker will need secondary access to fully carry out an attack using compromised components of the supply chain.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML Supply Chain Compromise"*

Table 7823. Table References

Links
https://atlas.mitre.org/techniques/AML.T0010

Hardware

Adversaries may target AI systems by disrupting or manipulating the hardware supply chain. AI models often run on specialized hardware such as GPUs, TPUs, or embedded devices, but may also be optimized to operate on CPUs.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Hardware"*

Table 7824. Table References

Links

https://atlas.mitre.org/techniques/AML.T0010.000

ML Software

Most machine learning systems rely on a limited set of machine learning frameworks. An adversary could get access to a large number of machine learning systems through a comprise of one of their supply chains. Many machine learning projects also rely on other open source implementations of various algorithms. These can also be compromised in a targeted way to get access to specific systems.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML Software"*

Table 7825. Table References

Links
https://atlas.mitre.org/techniques/AML.T0010.001

Data

Data is a key vector of supply chain compromise for adversaries. Every machine learning project will require some form of data. Many rely on large open source datasets that are publicly available. An adversary could rely on compromising these sources of data. The malicious data could be a result of [Poison Training Data](/techniques/AML.T0020) or include traditional malware.

An adversary can also target private datasets in the labeling phase. The creation of private datasets will often require the hiring of outside labeling services. An adversary can poison a dataset by modifying the labels being generated by the labeling service.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Data"*

Table 7826. Table References

Links
https://atlas.mitre.org/techniques/AML.T0010.002

Model

Machine learning systems often rely on open sourced models in various ways. Most commonly, the victim organization may be using these models for fine tuning. These models will be downloaded from an external source and then used as the base for the model as it is tuned on a smaller, private dataset. Loading models often requires executing some saved code in the form of a saved model file. These can be compromised with traditional malware, or through some adversarial machine learning techniques.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Model"*

Table 7827. Table References

Links
https://atlas.mitre.org/techniques/AML.T0010.003

User Execution

An adversary may rely upon specific actions by a user in order to gain execution. Users may inadvertently execute unsafe code introduced via [ML Supply Chain Compromise](/techniques/AML.T0010). Users may be subjected to social engineering to get them to execute malicious code by, for example, opening a malicious document file or link.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="User Execution"*

Table 7828. Table References

Links
https://atlas.mitre.org/techniques/AML.T0011

Unsafe ML Artifacts

Adversaries may develop unsafe ML artifacts that when executed have a deleterious effect. The adversary can use this technique to establish persistent access to systems. These models may be introduced via a [ML Supply Chain Compromise](/techniques/AML.T0010).

Serialization of models is a popular technique for model storage, transfer, and loading. However, this format without proper checking presents an opportunity for code execution.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Unsafe ML Artifacts"*

Table 7829. Table References

Links
https://atlas.mitre.org/techniques/AML.T0011.000

Malicious Package

Adversaries may develop malicious software packages that when imported by a user have a deleterious effect. Malicious packages may behave as expected to the user. They may be introduced via [ML Supply Chain Compromise](/techniques/AML.T0010). They may not present as obviously malicious to the user and may appear to be useful for an AI-related task.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Malicious Package"*

Table 7830. Table References

Links
https://atlas.mitre.org/techniques/AML.T0011.001

Valid Accounts

Adversaries may obtain and abuse credentials of existing accounts as a means of gaining Initial Access. Credentials may take the form of usernames and passwords of individual user accounts or API keys that provide access to various ML resources and services.

Compromised credentials may provide access to additional ML artifacts and allow the adversary to perform [Discover ML Artifacts](/techniques/AML.T0007). Compromised credentials may also grant an adversary increased privileges such as write access to ML artifacts used during development or production.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Valid Accounts"*

Table 7831. Table References

Links
https://atlas.mitre.org/techniques/AML.T0012

Discover ML Model Ontology

Adversaries may discover the ontology of a machine learning model's output space, for example, the types of objects a model can detect. The adversary may discovery the ontology by repeated queries to the model, forcing it to enumerate its output space. Or the ontology may be discovered in a configuration file or in documentation about the model.

The model ontology helps the adversary understand how the model is being used by the victim. It is useful to the adversary in creating targeted attacks.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Discover ML Model Ontology"*

Table 7832. Table References

Links
https://atlas.mitre.org/techniques/AML.T0013

Discover ML Model Family

Adversaries may discover the general family of model. General information about the model may be revealed in documentation, or the adversary may use carefully constructed examples and analyze the model's responses to categorize it.

Knowledge of the model family can help the adversary identify means of attacking the model and help tailor the attack.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Discover ML Model Family"*

Table 7833. Table References

Links

https://atlas.mitre.org/techniques/AML.T0014

Evade ML Model

Adversaries can [Craft Adversarial Data](/techniques/AML.T0043) that prevent a machine learning model from correctly identifying the contents of the data. This technique can be used to evade a downstream task where machine learning is utilized. The adversary may evade machine learning based virus/malware detection, or network scanning towards the goal of a traditional cyber attack.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Evade ML Model"*

Table 7834. Table References

Links
https://atlas.mitre.org/techniques/AML.T0015

Obtain Capabilities

Adversaries may search for and obtain software capabilities for use in their operations. Capabilities may be specific to ML-based attacks [Adversarial ML Attack Implementations](/techniques/AML.T0016.000) or generic software tools repurposed for malicious intent ([Software Tools](/techniques/AML.T0016.001)). In both instances, an adversary may modify or customize the capability to aid in targeting a particular ML system.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Obtain Capabilities"*

Table 7835. Table References

Links
https://atlas.mitre.org/techniques/AML.T0016

Adversarial ML Attack Implementations

Adversaries may search for existing open source implementations of machine learning attacks. The research community often publishes their code for reproducibility and to further future research. Libraries intended for research purposes, such as CleverHans, the Adversarial Robustness Toolbox, and FoolBox, can be weaponized by an adversary. Adversaries may also obtain and use tools that were not originally designed for adversarial ML attacks as part of their attack.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Adversarial ML Attack Implementations"*

Table 7836. Table References

Links
https://atlas.mitre.org/techniques/AML.T0016.000

Software Tools

Adversaries may search for and obtain software tools to support their operations. Software designed for legitimate use may be repurposed by an adversary for malicious intent. An adversary may modify or customize software tools to achieve their purpose. Software tools used to support attacks on ML systems are not necessarily ML-based themselves.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Software Tools"*

Table 7837. Table References

Links
https://atlas.mitre.org/techniques/AML.T0016.001

Develop Capabilities

Adversaries may develop their own capabilities to support operations. This process encompasses identifying requirements, building solutions, and deploying capabilities. Capabilities used to support attacks on ML systems are not necessarily ML-based themselves. Examples include setting up websites with adversarial information or creating Jupyter notebooks with obfuscated exfiltration code.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Develop Capabilities"*

Table 7838. Table References

Links
https://atlas.mitre.org/techniques/AML.T0017

Adversarial ML Attacks

Adversaries may develop their own adversarial attacks. They may leverage existing libraries as a starting point ([Adversarial ML Attack Implementations](/techniques/AML.T0016.000)). They may implement ideas described in public research papers or develop custom made attacks for the victim model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Adversarial ML Attacks"*

Table 7839. Table References

Links
https://atlas.mitre.org/techniques/AML.T0017.000

Backdoor ML Model

Adversaries may introduce a backdoor into a ML model. A backdoored model operates performs as expected under typical conditions, but will produce the adversary's desired output when a trigger is introduced to the input data. A backdoored model provides the adversary with a persistent

artifact on the victim system. The embedded vulnerability is typically activated at a later time by data samples with an [Insert Backdoor Trigger](/techniques/AML.T0043.004)

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Backdoor ML Model"*

Table 7840. Table References

Links
https://atlas.mitre.org/techniques/AML.T0018

Poison ML Model

Adversaries may introduce a backdoor by training the model poisoned data, or by interfering with its training process. The model learns to associate an adversary-defined trigger with the adversary's desired output.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Poison ML Model"*

Table 7841. Table References

Links
https://atlas.mitre.org/techniques/AML.T0018.000

Inject Payload

Adversaries may introduce a backdoor into a model by injecting a payload into the model file. The payload detects the presence of the trigger and bypasses the model, instead producing the adversary's desired output.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Inject Payload"*

Table 7842. Table References

Links
https://atlas.mitre.org/techniques/AML.T0018.001

Publish Poisoned Datasets

Adversaries may [Poison Training Data](/techniques/AML.T0020) and publish it to a public location. The poisoned dataset may be a novel dataset or a poisoned variant of an existing open source dataset. This data may be introduced to a victim system via [ML Supply Chain Compromise](/techniques/AML.T0010).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Publish Poisoned Datasets"*

Table 7843. Table References

Links
https://atlas.mitre.org/techniques/AML.T0019

Poison Training Data

Adversaries may attempt to poison datasets used by a ML model by modifying the underlying data or its labels. This allows the adversary to embed vulnerabilities in ML models trained on the data that may not be easily detectable. Data poisoning attacks may or may not require modifying the labels. The embedded vulnerability is activated at a later time by data samples with an [Insert Backdoor Trigger](/techniques/AML.T0043.004)

Poisoned data can be introduced via [ML Supply Chain Compromise](/techniques/AML.T0010) or the data may be poisoned after the adversary gains [Initial Access](/tactics/AML.TA0004) to the system.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Poison Training Data"*

Table 7844. Table References

Links
https://atlas.mitre.org/techniques/AML.T0020

Establish Accounts

Adversaries may create accounts with various services for use in targeting, to gain access to resources needed in [ML Attack Staging](/tactics/AML.TA0001), or for victim impersonation.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Establish Accounts"*

Table 7845. Table References

Links
https://atlas.mitre.org/techniques/AML.T0021

Exfiltration via ML Inference API

Adversaries may exfiltrate private information via [AI Model Inference API Access](/techniques/AML.T0040). ML Models have been shown leak private information about their training data (e.g. [Infer Training Data Membership](/techniques/AML.T0024.000), [Invert ML Model](/techniques/AML.T0024.001)). The model itself may also be extracted ([Extract ML Model](/techniques/AML.T0024.002)) for the purposes of [ML Intellectual Property Theft](/techniques/AML.T0048.004).

Exfiltration of information relating to private training data raises privacy concerns. Private training data may include personally identifiable information, or other protected data.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Exfiltration via ML Inference API"*

Table 7846. Table References

Links
https://atlas.mitre.org/techniques/AML.T0024

Infer Training Data Membership

Adversaries may infer the membership of a data sample in its training set, which raises privacy concerns. Some strategies make use of a shadow model that could be obtained via [Train Proxy via Replication](/techniques/AML.T0005.001), others use statistics of model prediction scores.

This can cause the victim model to leak private information, such as PII of those in the training set or other forms of protected IP.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Infer Training Data Membership"*

Table 7847. Table References

Links
https://atlas.mitre.org/techniques/AML.T0024.000

Invert ML Model

Machine learning models' training data could be reconstructed by exploiting the confidence scores that are available via an inference API. By querying the inference API strategically, adversaries can back out potentially private information embedded within the training data. This could lead to privacy violations if the attacker can reconstruct the data of sensitive features used in the algorithm.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Invert ML Model"*

Table 7848. Table References

Links
https://atlas.mitre.org/techniques/AML.T0024.001

Extract ML Model

Adversaries may extract a functional copy of a private model. By repeatedly querying the victim's [AI Model Inference API Access](/techniques/AML.T0040), the adversary can collect the target model's inferences into a dataset. The inferences are used as labels for training a separate model offline that will mimic the behavior and performance of the target model.

Adversaries may extract the model to avoid paying per query in a machine learning as a service setting. Model extraction is used for [ML Intellectual Property Theft](/techniques/AML.T0048.004).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Extract ML Model"*

Table 7849. Table References

Links
https://atlas.mitre.org/techniques/AML.T0024.002

Exfiltration via Cyber Means

Adversaries may exfiltrate ML artifacts or other information relevant to their goals via traditional cyber means.

See the ATT&CK [Exfiltration](https://attack.mitre.org/tactics/TA0010/) tactic for more information.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Exfiltration via Cyber Means"*

Table 7850. Table References

Links
https://atlas.mitre.org/techniques/AML.T0025

Denial of ML Service

Adversaries may target machine learning systems with a flood of requests for the purpose of degrading or shutting down the service. Since many machine learning systems require significant amounts of specialized compute, they are often expensive bottlenecks that can become overloaded. Adversaries can intentionally craft inputs that require heavy amounts of useless compute from the machine learning system.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Denial of ML Service"*

Table 7851. Table References

Links
https://atlas.mitre.org/techniques/AML.T0029

Erode ML Model Integrity

Adversaries may degrade the target model's performance with adversarial data inputs to erode confidence in the system over time. This can lead to the victim organization wasting time and money both attempting to fix the system and performing the tasks it was meant to automate by hand.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Erode ML Model Integrity"*

Table 7852. Table References

Links
https://atlas.mitre.org/techniques/AML.T0031

Cost Harvesting

Adversaries may target different machine learning services to send useless queries or computationally expensive inputs to increase the cost of running services at the victim organization. Sponge examples are a particular type of adversarial data designed to maximize

energy consumption and thus operating cost.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Cost Harvesting"*

Table 7853. Table References

Links
https://atlas.mitre.org/techniques/AML.T0034

ML Artifact Collection

Adversaries may collect ML artifacts for [Exfiltration](/tactics/AML.TA0010) or for use in [ML Attack Staging](/tactics/AML.TA0001). ML artifacts include models and datasets as well as other telemetry data produced when interacting with a model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML Artifact Collection"*

Table 7854. Table References

Links
https://atlas.mitre.org/techniques/AML.T0035

Data from Information Repositories

Adversaries may leverage information repositories to mine valuable information. Information repositories are tools that allow for storage of information, typically to facilitate collaboration or information sharing between users, and can store a wide variety of data that may aid adversaries in further objectives, or direct access to the target information.

Information stored in a repository may vary based on the specific instance or environment. Specific common information repositories include SharePoint, Confluence, and enterprise databases such as SQL Server.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Data from Information Repositories"*

Table 7855. Table References

Links
https://atlas.mitre.org/techniques/AML.T0036

Data from Local System

Adversaries may search local system sources, such as file systems and configuration files or local databases, to find files of interest and sensitive data prior to Exfiltration.

This can include basic fingerprinting information and sensitive data such as ssh keys.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Data from Local System"*

Table 7856. Table References

Links
https://atlas.mitre.org/techniques/AML.T0037

AI Model Inference API Access

Adversaries may gain access to a model via legitimate access to the inference API. Inference API access can be a source of information to the adversary ([Discover ML Model Ontology](/techniques/AML.T0013), [Discover ML Model Family](/techniques/AML.T0014)), a means of staging the attack ([Verify Attack](/techniques/AML.T0042), [Craft Adversarial Data](/techniques/AML.T0043)), or for introducing data to the target system for Impact ([Evade ML Model](/techniques/AML.T0015), [Erode ML Model Integrity](/techniques/AML.T0031)).

Many systems rely on the same models provided via an inference API, which means they share the same vulnerabilities. This is especially true of foundation models which are prohibitively resource intensive to train. Adversaries may use their access to model APIs to identify vulnerabilities such as jailbreaks or hallucinations and then target applications that use the same models.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="AI Model Inference API Access"*

Table 7857. Table References

Links
https://atlas.mitre.org/techniques/AML.T0040

Physical Environment Access

In addition to the attacks that take place purely in the digital domain, adversaries may also exploit the physical environment for their attacks. If the model is interacting with data collected from the real world in some way, the adversary can influence the model through access to wherever the data is being collected. By modifying the data in the collection process, the adversary can perform modified versions of attacks designed for digital access.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Physical Environment Access"*

Table 7858. Table References

Links
https://atlas.mitre.org/techniques/AML.T0041

Verify Attack

Adversaries can verify the efficacy of their attack via an inference API or access to an offline copy of the target model. This gives the adversary confidence that their approach works and allows them to carry out the attack at a later time of their choosing. The adversary may verify the attack once but use it against many edge devices running copies of the target model. The adversary may verify their attack digitally, then deploy it in the [Physical Environment Access](/techniques/AML.T0041) at

a later time. Verifying the attack may be hard to detect since the adversary can use a minimal number of queries or an offline copy of the model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Verify Attack"*

Table 7859. Table References

Links
https://atlas.mitre.org/techniques/AML.T0042

Craft Adversarial Data

Adversarial data are inputs to a machine learning model that have been modified such that they cause the adversary's desired effect in the target model. Effects can range from misclassification, to missed detections, to maximizing energy consumption. Typically, the modification is constrained in magnitude or location so that a human still perceives the data as if it were unmodified, but human perceptibility may not always be a concern depending on the adversary's intended effect. For example, an adversarial input for an image classification task is an image the machine learning model would misclassify, but a human would still recognize as containing the correct class.

Depending on the adversary's knowledge of and access to the target model, the adversary may use different classes of algorithms to develop the adversarial example such as [White-Box Optimization](/techniques/AML.T0043.000), [Black-Box Optimization](/techniques/AML.T0043.001), [Black-Box Transfer](/techniques/AML.T0043.002), or [Manual Modification](/techniques/AML.T0043.003).

The adversary may [Verify Attack](/techniques/AML.T0042) their approach works if they have white-box or inference API access to the model. This allows the adversary to gain confidence their attack is effective "live" environment where their attack may be noticed. They can then use the attack at a later time to accomplish their goals. An adversary may optimize adversarial examples for [Evade ML Model](/techniques/AML.T0015), or to [Erode ML Model Integrity](/techniques/AML.T0031).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Craft Adversarial Data"*

Table 7860. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043

White-Box Optimization

In White-Box Optimization, the adversary has full access to the target model and optimizes the adversarial example directly. Adversarial examples trained in this manner are most effective against the target model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="White-Box Optimization"*

Table 7861. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043.000

Black-Box Optimization

In Black-Box attacks, the adversary has black-box (i.e. [AI Model Inference API Access](/techniques/AML.T0040) via API access) access to the target model. With black-box attacks, the adversary may be using an API that the victim is monitoring. These attacks are generally less effective and require more inferences than [White-Box Optimization](/techniques/AML.T0043.000) attacks, but they require much less access.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Black-Box Optimization"*

Table 7862. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043.001

Black-Box Transfer

In Black-Box Transfer attacks, the adversary uses one or more proxy models (trained via [Create Proxy ML Model](/techniques/AML.T0005) or [Train Proxy via Replication](/techniques/AML.T0005.001)) they have full access to and are representative of the target model. The adversary uses [White-Box Optimization](/techniques/AML.T0043.000) on the proxy models to generate adversarial examples. If the set of proxy models are close enough to the target model, the adversarial example should generalize from one to another. This means that an attack that works for the proxy models will likely then work for the target model. If the adversary has [AI Model Inference API Access](/techniques/AML.T0040), they may use [Verify Attack](/techniques/AML.T0042) to confirm the attack is working and incorporate that information into their training process.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Black-Box Transfer"*

Table 7863. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043.002

Manual Modification

Adversaries may manually modify the input data to craft adversarial data. They may use their knowledge of the target model to modify parts of the data they suspect helps the model in performing its task. The adversary may use trial and error until they are able to verify they have a working adversarial input.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Manual Modification"*

Table 7864. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043.003

Insert Backdoor Trigger

The adversary may add a perceptual trigger into inference data. The trigger may be imperceptible or non-obvious to humans. This technique is used in conjunction with [Poison ML Model](/techniques/AML.T0018.000) and allows the adversary to produce their desired effect in the target model.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Insert Backdoor Trigger"*

Table 7865. Table References

Links
https://atlas.mitre.org/techniques/AML.T0043.004

Full ML Model Access

Adversaries may gain full "white-box" access to a machine learning model. This means the adversary has complete knowledge of the model architecture, its parameters, and class ontology. They may exfiltrate the model to [Craft Adversarial Data](/techniques/AML.T0043) and [Verify Attack](/techniques/AML.T0042) in an offline where it is hard to detect their behavior.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Full ML Model Access"*

Table 7866. Table References

Links
https://atlas.mitre.org/techniques/AML.T0044

Spamming ML System with Chaff Data

Adversaries may spam the machine learning system with chaff data that causes increase in the number of detections. This can cause analysts at the victim organization to waste time reviewing and correcting incorrect inferences.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Spamming ML System with Chaff Data"*

Table 7867. Table References

Links
https://atlas.mitre.org/techniques/AML.T0046

ML-Enabled Product or Service

Adversaries may use a product or service that uses machine learning under the hood to gain access to the underlying machine learning model. This type of indirect model access may reveal details of the ML model or its inferences in logs or metadata.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML-Enabled Product or Service"*

https://atlas.mitre.org/techniques/AML.T0047

External Harms

Adversaries may abuse their access to a victim system and use its resources or capabilities to further their goals by causing harms external to that system. These harms could affect the organization (e.g. Financial Harm, Reputational Harm), its users (e.g. User Harm), or the general public (e.g. Societal Harm).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="External Harms"*

Table 7869. Table References

Links
https://atlas.mitre.org/techniques/AML.T0048

Financial Harm

Financial harm involves the loss of wealth, property, or other monetary assets due to theft, fraud or forgery, or pressure to provide financial resources to the adversary.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Financial Harm"*

Table 7870. Table References

Links
https://atlas.mitre.org/techniques/AML.T0048.000

Reputational Harm

Reputational harm involves a degradation of public perception and trust in organizations. Examples of reputation-harming incidents include scandals or false impersonations.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Reputational Harm"*

Table 7871. Table References

Links

https://atlas.mitre.org/techniques/AML.T0048.001

Societal Harm

Societal harms might generate harmful outcomes that reach either the general public or specific vulnerable groups such as the exposure of children to vulgar content.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Societal Harm"*

Table 7872. Table References

Links
https://atlas.mitre.org/techniques/AML.T0048.002

User Harm

User harms may encompass a variety of harm types including financial and reputational that are directed at or felt by individual victims of the attack rather than at the organization level.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="User Harm"*

Table 7873. Table References

Links
https://atlas.mitre.org/techniques/AML.T0048.003

ML Intellectual Property Theft

Adversaries may exfiltrate ML artifacts to steal intellectual property and cause economic harm to the victim organization.

Proprietary training data is costly to collect and annotate and may be a target for [Exfiltration](/tactics/AML.TA0010) and theft.

MLaaS providers charge for use of their API. An adversary who has stolen a model via [Exfiltration](/tactics/AML.TA0010) or via [Extract ML Model](/techniques/AML.T0024.002) now has unlimited use of that service without paying the owner of the intellectual property.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="ML Intellectual Property Theft"*

Table 7874. Table References

Links
https://atlas.mitre.org/techniques/AML.T0048.004

Exploit Public-Facing Application

Adversaries may attempt to take advantage of a weakness in an Internet-facing computer or

program using software, data, or commands in order to cause unintended or unanticipated behavior. The weakness in the system can be a bug, a glitch, or a design vulnerability. These applications are often websites, but can include databases (like SQL), standard services (like SMB or SSH), network device administration and management protocols (like SNMP and Smart Install), and any other applications with Internet accessible open sockets, such as web servers and related services.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Exploit Public-Facing Application"*

Table 7875. Table References

Links
https://atlas.mitre.org/techniques/AML.T0049

Command and Scripting Interpreter

Adversaries may abuse command and script interpreters to execute commands, scripts, or binaries. These interfaces and languages provide ways of interacting with computer systems and are a common feature across many different platforms. Most systems come with some built-in command-line interface and scripting capabilities, for example, macOS and Linux distributions include some flavor of Unix Shell while Windows installations include the Windows Command Shell and PowerShell.

There are also cross-platform interpreters such as Python, as well as those commonly associated with client applications such as JavaScript and Visual Basic.

Adversaries may abuse these technologies in various ways as a means of executing arbitrary commands. Commands and scripts can be embedded in Initial Access payloads delivered to victims as lure documents or as secondary payloads downloaded from an existing C2. Adversaries may also execute commands through interactive terminals/shells, as well as utilize various Remote Services in order to achieve remote Execution.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Command and Scripting Interpreter"*

Table 7876. Table References

Links
https://atlas.mitre.org/techniques/AML.T0050

LLM Prompt Injection

An adversary may craft malicious prompts as inputs to an LLM that cause the LLM to act in unintended ways. These "prompt injections" are often designed to cause the model to ignore aspects of its original instructions and follow the adversary’s instructions instead.

Prompt Injections can be an initial access vector to the LLM that provides the adversary with a foothold to carry out other steps in their operation. They may be designed to bypass defenses in the LLM, or allow the adversary to issue privileged commands. The effects of a prompt injection can persist throughout an interactive session with an LLM.

Malicious prompts may be injected directly by the adversary ([Direct](/techniques/AML.T0051.000)) either to leverage the LLM to generate harmful content or to gain a foothold on the system and lead to further effects. Prompts may also be injected indirectly when as part of its normal operation the LLM ingests the malicious prompt from another data source ([Indirect](/techniques/AML.T0051.001)). This type of injection can be used by the adversary to a foothold on the system or to target the user of the LLM.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Prompt Injection"*

Table 7877. Table References

Links
https://atlas.mitre.org/techniques/AML.T0051

Direct

An adversary may inject prompts directly as a user of the LLM. This type of injection may be used by the adversary to gain a foothold in the system or to misuse the LLM itself, as for example to generate harmful content.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Direct"*

Table 7878. Table References

Links
https://atlas.mitre.org/techniques/AML.T0051.000

Indirect

An adversary may inject prompts indirectly via separate data channel ingested by the LLM such as include text or multimedia pulled from databases or websites. These malicious prompts may be hidden or obfuscated from the user. This type of injection may be used by the adversary to gain a foothold in the system or to target an unwitting user of the system.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Indirect"*

Table 7879. Table References

Links
https://atlas.mitre.org/techniques/AML.T0051.001

Phishing

Adversaries may send phishing messages to gain access to victim systems. All forms of phishing are electronically delivered social engineering. Phishing can be targeted, known as spearphishing. In spearphishing, a specific individual, company, or industry will be targeted by the adversary. More generally, adversaries can conduct non-targeted phishing, such as in mass malware spam campaigns.

Generative AI, including LLMs that generate synthetic text, visual deepfakes of faces, and audio deepfakes of speech, is enabling adversaries to scale targeted phishing campaigns. LLMs can interact with users via text conversations and can be programmed with a meta prompt to phish for sensitive information. Deepfakes can be use in impersonation as an aid to phishing.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Phishing"*

Table 7880. Table References

Links
https://atlas.mitre.org/techniques/AML.T0052

Spearphishing via Social Engineering LLM

Adversaries may turn LLMs into targeted social engineers. LLMs are capable of interacting with users via text conversations. They can be instructed by an adversary to seek sensitive information from a user and act as effective social engineers. They can be targeted towards particular personas defined by the adversary. This allows adversaries to scale spearphishing efforts and target individuals to reveal private information such as credentials to privileged systems.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Spearphishing via Social Engineering LLM"*

Table 7881. Table References

Links
https://atlas.mitre.org/techniques/AML.T0052.000

LLM Plugin Compromise

Adversaries may use their access to an LLM that is part of a larger system to compromise connected plugins. LLMs are often connected to other services or resources via plugins to increase their capabilities. Plugins may include integrations with other applications, access to public or private data sources, and the ability to execute code.

This may allow adversaries to execute API calls to integrated applications or plugins, providing the adversary with increased privileges on the system. Adversaries may take advantage of connected data sources to retrieve sensitive information. They may also use an LLM integrated with a command or script interpreter to execute arbitrary instructions.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Plugin Compromise"*

Table 7882. Table References

Links
https://atlas.mitre.org/techniques/AML.T0053

LLM Jailbreak

An adversary may use a carefully crafted [LLM Prompt Injection](/techniques/AML.T0051) designed to place LLM in a state in which it will freely respond to any user input, bypassing any controls, restrictions, or guardrails placed on the LLM. Once successfully jailbroken, the LLM can be used in unintended ways by the adversary.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Jailbreak"*

Table 7883. Table References

Links
https://atlas.mitre.org/techniques/AML.T0054

Unsecured Credentials

Adversaries may search compromised systems to find and obtain insecurely stored credentials. These credentials can be stored and/or misplaced in many locations on a system, including plaintext files (e.g. bash history), environment variables, operating system, or application-specific repositories (e.g. Credentials in Registry), or other specialized files/artifacts (e.g. private keys).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Unsecured Credentials"*

Table 7884. Table References

Links
https://atlas.mitre.org/techniques/AML.T0055

LLM Meta Prompt Extraction

An adversary may induce an LLM to reveal its initial instructions, or "meta prompt." Discovering the meta prompt can inform the adversary about the internal workings of the system. Prompt engineering is an emerging field that requires expertise and exfiltrating the meta prompt can prompt in order to steal valuable intellectual property.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Meta Prompt Extraction"*

Table 7885. Table References

Links
https://atlas.mitre.org/techniques/AML.T0056

LLM Data Leakage

Adversaries may craft prompts that induce the LLM to leak sensitive information. This can include private user data or proprietary information. The leaked information may come from proprietary training data, data sources the LLM is connected to, or information from other users of the LLM.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Data Leakage"*

Table 7886. Table References

Links
https://atlas.mitre.org/techniques/AML.T0057

Publish Poisoned Models

Adversaries may publish a poisoned model to a public location such as a model registry or code repository. The poisoned model may be a novel model or a poisoned variant of an existing open-source model. This model may be introduced to a victim system via [ML Supply Chain Compromise](/techniques/AML.T0010).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Publish Poisoned Models"*

Table 7887. Table References

Links
https://atlas.mitre.org/techniques/AML.T0058

Erode Dataset Integrity

Adversaries may poison or manipulate portions of a dataset to reduce its usefulness, reduce trust, and cause users to waste resources correcting errors.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Erode Dataset Integrity"*

Table 7888. Table References

Links
https://atlas.mitre.org/techniques/AML.T0059

Publish Hallucinated Entities

Adversaries may create an entity they control, such as a software package, website, or email address to a source hallucinated by an LLM. The hallucinations may take the form of package names commands, URLs, company names, or email addresses that point the victim to the entity controlled by the adversary. When the victim interacts with the adversary-controlled entity, the attack can proceed.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Publish Hallucinated Entities"*

Table 7889. Table References

Links
https://atlas.mitre.org/techniques/AML.T0060

LLM Prompt Self-Replication

An adversary may use a carefully crafted [LLM Prompt Injection](/techniques/AML.T0051) designed to cause the LLM to replicate the prompt as part of its output. This allows the prompt to propagate to other LLMs and persist on the system. The self-replicating prompt is typically paired with other malicious instructions (ex: [LLM Jailbreak](/techniques/AML.T0054), [LLM Data Leakage](/techniques/AML.T0057)).

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="LLM Prompt Self-Replication"*

Table 7890. Table References

Links
https://atlas.mitre.org/techniques/AML.T0061

Discover LLM Hallucinations

Adversaries may prompt large language models and identify hallucinated entities. They may request software packages, commands, URLs, organization names, or e-mail addresses, and identify hallucinations with no connected real-world source. Discovered hallucinations provide the adversary with potential targets to [Publish Hallucinated Entities](/techniques/AML.T0060). Different LLMs have been shown to produce the same hallucinations, so the hallucinations exploited by an adversary may affect users of other LLMs.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Discover LLM Hallucinations"*

Table 7891. Table References

Links
https://atlas.mitre.org/techniques/AML.T0062

Discover AI Model Outputs

Adversaries may discover model outputs, such as class scores, whose presence is not required for the system to function and are not intended for use by the end user. Model outputs may be found in logs or may be included in API responses. Model outputs may enable the adversary to identify weaknesses in the model and develop attacks.

The tag is: *misp-galaxy:mitre-atlas-attack-pattern="Discover AI Model Outputs"*

authors

MITRE

Limit Public Release of Information

Limit the public release of technical information about the machine learning stack used in an organization's products or services. Technical knowledge of how machine learning is used can be leveraged by adversaries to perform targeting and tailor attacks to the target system. Additionally, consider limiting the release of organizational information - including physical locations, researcher names, and department structures - from which technical details such as machine learning techniques, model architectures, or datasets may be inferred.

The tag is: *misp-galaxy:mitre-atlas-course-of-action="Limit Public Release of Information"*

View relationships graph

Limit Public Release of Information has relationships with:

- mitigates: misp-galaxy:mitre-atlas-attack-pattern="Search for Victim's Publicly Available Research Materials" with estimative-language:likelihood-probability="almost-certain"
- mitigates: misp-galaxy:mitre-atlas-attack-pattern="Search Application Repositories" with estimative-language:likelihood-probability="almost-certain"

Vulnerability Scanning

Vulnerability scanning is used to find potentially exploitable software vulnerabilities to remediate

them.

File formats such as pickle files that are commonly used to store machine learning models can contain exploits that allow for arbitrary code execution. Both model artifacts and downstream products produced by models should be scanned for known vulnerabilities.

Model Distribution Methods

Deploying ML models to edge devices can increase the attack surface of the system. Consider serving models in the cloud to reduce the level of access the adversary has to the model. Also consider computing features in the cloud to prevent gray-box attacks, where an adversary has access to the model preprocessing methods.

Generative AI Guardrails

Guardrails are safety controls that are placed between a generative AI model and the output shared with the user to prevent undesired inputs and outputs. Guardrails can take the form of validators such as filters, rule-based logic, or regular expressions, as well as AI-based approaches, such as

classifiers and utilizing LLMs, or named entity recognition (NER) to evaluate the safety of the prompt or response. Domain specific methods can be employed to reduce risks in a variety of areas such as etiquette, brand damage, jailbreaking, false information, code exploits, SQL injections, and data leakage.

Generative AI Guidelines

Guidelines are safety controls that are placed between user-provided input and a generative AI model to help direct the model to produce desired outputs and prevent undesired outputs.

Guidelines can be implemented as instructions appended to all user prompts or as part of the instructions in the system prompt. They can define the goal(s), role, and voice of the system, as well as outline safety and security parameters.

Generative AI Model Alignment

When training or fine-tuning a generative AI model it is important to utilize techniques that improve model alignment with safety, security, and content policies.

The fine-tuning process can potentially remove built-in safety mechanisms in a generative AI model, but utilizing techniques such as Supervised Fine-Tuning, Reinforcement Learning from Human Feedback or AI Feedback, and Targeted Safety Context Distillation can improve the safety and alignment of the model.

Test ability to evade automated mobile application security analysis performed by app stores - T1393

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](http://attack.mitre.org/matrices/enterprise/pre/) matrix for its replacement. The prior content of this page has been preserved [here](https://attack.mitre.org/versions/v7/techniques/T1393).

Many mobile devices are configured to only allow applications to be installed from the mainstream vendor app stores (e.g., Apple App Store and Google Play Store). An adversary can submit multiple code samples to these stores deliberately designed to probe the stores' security analysis capabilities, with the goal of determining effective techniques to place malicious applications in the stores that could then be delivered to targeted devices. (Citation: Android Bouncer) (Citation: Adventures in BouncerLand) (Citation: Jekyll on iOS) (Citation: Fruit vs Zombies)

Linux and Mac File and Directory Permissions Modification - T1222.002

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Most Linux and Linux-based platforms provide a standard set of permission groups (user, group, and other) and a standard set of permissions (read, write, and execute) that are applied to each group. While nuances of each platform's permissions implementation may vary, most of the platforms provide two primary commands used to manipulate file and directory ACLs: <code>chown</code> (short for change owner), and <code>chmod</code> (short for change mode).

Adversarial may use these commands to make themselves the owner of files and directories or change the mode if current permissions allow it. They could subsequently lock others out of the file. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [Unix Shell Configuration Modification](https://attack.mitre.org/techniques/T1546/004) or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](https://attack.mitre.org/techniques/T1574).(Citation: 20 macOS Common Tools and Techniques)

Abuse of iOS Enterprise App Signing Key - T1445

An adversary could abuse an iOS enterprise app signing key (intended for enterprise in-house distribution of apps) to sign malicious iOS apps so that they can be installed on iOS devices without the app needing to be published on Apple's App Store. For example, Xiao describes use of this technique in (Citation: Xiao-iOS).

Detection: iOS 9 and above typically requires explicit user consent before allowing installation of applications signed with enterprise distribution keys rather than installed from Apple's App Store.

Platforms: iOS

The tag is: *misp-galaxy:mitre-attack-pattern="Abuse of iOS Enterprise App Signing Key - T1445"*

Deliver Malicious App via Authorized App Store - T1475

Malicious applications are a common attack vector used by adversaries to gain a presence on mobile devices. Mobile devices often are configured to allow application installation only from an authorized app store (e.g., Google Play Store or Apple App Store). An adversary may seek to place a malicious application in an authorized app store, enabling the application to be installed onto targeted devices.

App stores typically require developer registration and use vetting techniques to identify malicious applications. Adversaries may use these techniques against app store defenses:

- [Download New Code at Runtime](https://attack.mitre.org/techniques/T1407)
- [Obfuscated Files or Information](https://attack.mitre.org/techniques/T1406)

Adversaries may also seek to evade vetting by placing code in a malicious application to detect whether it is running in an app analysis environment and, if so, avoid performing malicious actions while under analysis. (Citation: Petsas) (Citation: Oberheide-Bouncer) (Citation: Percoco-Bouncer) (Citation: Wang)

Adversaries may also use fake identities, payment cards, etc., to create developer accounts to publish malicious applications to app stores. (Citation: Oberheide-Bouncer)

Adversaries may also use control of a target's Google account to use the Google Play Store's remote installation capability to install apps onto the Android devices associated with the Google account. (Citation: Oberheide-RemoteInstall) (Citation: Konoth) (Only applications that are available for download through the Google Play Store can be remotely installed using this technique.)

Exfiltration Over Symmetric Encrypted Non-C2 Protocol - T1048.001

Adversaries may steal data by exfiltrating it over a symmetrically encrypted network protocol other than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Symmetric encryption algorithms are those that use shared or the same keys/secrets on each end of the channel. This requires an exchange or pre-arranged agreement/possession of the value used to encrypt and decrypt data.

Network protocols that use asymmetric encryption often utilize symmetric encryption once keys are exchanged, but adversaries may opt to manually share keys and implement symmetric cryptographic algorithms (ex: RC4, AES) vice using mechanisms that are baked into a protocol. This may result in multiple layers of encryption (in protocols that are natively encrypted such as HTTPS) or encryption in protocols that not typically encrypted (such as HTTP or FTP).

Exfiltration Over Asymmetric Encrypted Non-C2 Protocol - T1048.002

Adversaries may steal data by exfiltrating it over an asymmetrically encrypted network protocol other than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Asymmetric encryption algorithms are those that use different keys on each end of the channel. Also known as public-key cryptography, this requires pairs of cryptographic keys that can encrypt/decrypt data from the corresponding key. Each end of the communication channels requires a private key (only in the procession of that entity) and the public key of the other entity.

The public keys of each entity are exchanged before encrypted communications begin.

Network protocols that use asymmetric encryption (such as HTTPS/TLS/SSL) often utilize symmetric encryption once keys are exchanged. Adversaries may opt to use these encrypted mechanisms that are baked into a protocol.

Registry Run Keys / Startup Folder - T1547.001

Adversaries may achieve persistence by adding a program to a startup folder or referencing it with a Registry run key. Adding an entry to the "run keys" in the Registry or startup folder will cause the program referenced to be executed when a user logs in.(Citation: Microsoft Run Key) These programs will be executed under the context of the user and will have the account's associated permissions level.

The following run keys are created by default on Windows systems:

- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Run</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce</code>
- <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Run</code>
- <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce</code>

Run keys may exist under multiple hives.(Citation: Microsoft Wow6432Node 2018)(Citation: Malwarebytes Wow6432Node 2016) The <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnceEx</code> is also available but is not created by default on Windows Vista and newer. Registry run key entries can reference programs directly or list them as a dependency.(Citation: Microsoft Run Key) For example, it is possible to load a DLL at logon using a "Depend" key with RunOnceEx: <code>reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx\0001\Depend /v 1 /d "C:\temp\evil[.]dll"</code> (Citation: Oddvar Moe RunOnceEx Mar 2018)

Placing a program within a startup folder will also cause that program to execute when a user logs in. There is a startup folder location for individual user accounts as well as a system-wide startup folder that will be checked regardless of which user account logs in. The startup folder path for the current user is <code>C:\Users\\[Username]\AppData\Roaming\Microsoft\Windows\Start Menu\Programs\Startup</code>. The startup folder path for all users is <code>C:\ProgramData\Microsoft\Windows\Start Menu\Programs\StartUp</code>.

The following Registry keys can be used to set startup folder items for persistence:

- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code>
- <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code>
- <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code>

The following Registry keys can control automatic startup of services during boot:

- <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</

code>

- <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServices</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServices</code>

Using policy settings to specify startup programs creates corresponding values in either of two Registry keys:

- <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run</code>

Programs listed in the load value of the registry key <code>HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Windows</code> run automatically for the currently logged-on user.

By default, the multistring <code>BootExecute</code> value of the registry key <code>HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager</code> is set to <code>autocheck autochk *</code>. This value causes Windows, at startup, to check the file-system integrity of the hard disks if the system has been shut down abnormally. Adversaries can add other programs or processes to this registry value which will automatically launch at boot.

Adversaries can use these configuration locations to execute malware, such as remote access tools, to maintain persistence through system reboots. Adversaries may also use [Masquerading](https://attack.mitre.org/techniques/T1036) to make the Registry entries look as if they are associated with legitimate programs.

Clear Linux or Mac System Logs - T1070.002

Adversaries may clear system logs to hide evidence of an intrusion. macOS and Linux both keep track of system or user-initiated actions via system logs. The majority of native system logging is stored under the <code>/var/log/</code> directory. Subfolders in this directory categorize logs by

their related functions, such as:(Citation: Linux Logs)

- <code>/var/log/messages:</code>: General and system-related messages
- <code>/var/log/secure</code> or <code>/var/log/auth.log</code>: Authentication logs
- <code>/var/log/utmp</code> or <code>/var/log/wtmp</code>: Login records
- <code>/var/log/kern.log</code>: Kernel logs
- <code>/var/log/cron.log</code>: Crond logs
- <code>/var/log/maillog</code>: Mail server logs
- <code>/var/log/httpd/</code>: Web server access and error logs

The tag is: *misp-galaxy:mitre-attack-pattern="Clear Linux or Mac System Logs - T1070.002"*

Clear Network Connection History and Configurations - T1070.007

Adversaries may clear or remove evidence of malicious network connections in order to clean up traces of their operations. Configuration settings as well as various artifacts that highlight connection history may be created on a system and/or in application logs from behaviors that require network connections, such as [Remote Services](https://attack.mitre.org/techniques/T1021) or [External Remote Services](https://attack.mitre.org/techniques/T1133). Defenders may use these artifacts to monitor or otherwise analyze network connections created by adversaries.

Network connection history may be stored in various locations. For example, RDP connection history may be stored in Windows Registry values under (Citation: Microsoft RDP Removal):

- <code>HKEY_CURRENT_USER\Software\Microsoft\Terminal Server Client\Default</code>
- <code>HKEY_CURRENT_USER\Software\Microsoft\Terminal Server Client\Servers</code>

Windows may also store information about recent RDP connections in files such as <code>C:\Users\\%username%\Documents\Default.rdp</code> and `C:\Users\%username%\AppData\Local\Microsoft\Terminal Server Client\Cache\`.(Citation: Moran RDPieces) Similarly, macOS and Linux hosts may store information highlighting connection history in system logs (such as those stored in `/Library/Logs` and/or `/var/log/`).(Citation: Apple Culprit Access)(Citation: FreeDesktop Journal)(Citation: Apple Unified Log Analysis Remote Login and Screen Sharing)

Malicious network connections may also require changes to third-party applications or network configuration settings, such as [Disable or Modify System Firewall](https://attack.mitre.org/techniques/T1562/004) or tampering to enable [Proxy](https://attack.mitre.org/techniques/T1090).

Adversaries may delete or modify this data to conceal indicators and/or impede defensive analysis.

Match Legitimate Resource Name or Location - T1036.005

Adversaries may match or approximate the name or location of legitimate files, Registry keys, or other resources when naming/placing them. This is done for the sake of evading defenses and observation.

This may be done by placing an executable in a commonly trusted directory (ex: under System32) or giving it the name of a legitimate, trusted program (ex: `svchost.exe`). Alternatively, a Windows Registry key may be given a close approximation to a key used by a legitimate program. In containerized environments, a threat actor may create a resource in a trusted namespace or one that matches the naming convention of a container pod or cluster.(Citation: Aquasec Kubernetes Backdoor 2023)

Compromise Software Dependencies and Development Tools - T1195.001

Adversaries may manipulate software dependencies and development tools prior to receipt by a final consumer for the purpose of data or system compromise. Applications often depend on external software to function properly. Popular open source projects that are used as dependencies in many applications, such as pip and NPM packages, may be targeted as a means to add malicious code to users of the dependency.(Citation: Trendmicro NPM Compromise)(Citation: Bitdefender NPM Repositories Compromised 2021)(Citation: MANDVI Malicious npm and PyPI Packages Disguised) This may also include abandoned packages, which in some cases could be re-registered by threat actors after being removed by adversaries.(Citation: The Hacker News PyPi Revival Hijack 2024) Adversaries may also employ "typosquatting" or name-confusion by choosing names similar to existing popular libraries or packages in order to deceive a user.(Citation: Ahmed Backdoors in Python and NPM Packages)(Citation: Meyer PyPI Supply Chain Attack Uncovered)(Citation: Checkmarx-oss-seo)

Additionally, CI/CD pipeline components, such as GitHub Actions, may be targeted in order to gain access to the building, testing, and deployment cycles of an application.(Citation: Unit 42 Palo Alto GitHub Actions Supply Chain Attack 2025) By adding malicious code into a GitHub action, a threat actor may be able to collect runtime credentials (e.g., via [Proc Filesystem](https://attack.mitre.org/techniques/T1003/007)) or insert further malicious components into the build pipelines for a second-order supply chain compromise.(Citation: OWASP CICD-SEC-4) As GitHub Actions are often dependent on other GitHub Actions, threat actors may be able to infect a large number of repositories via the compromise of a single Action.(Citation: Palo Alto Networks GitHub Actions Worm 2023)

Targeting may be specific to a desired victim set or may be distributed to a broad set of consumers but only move on to additional tactics on specific victims.

Windows File and Directory Permissions Modification - T1222.001

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Windows implements file and directory ACLs as Discretionary Access Control Lists (DACLs).(Citation: Microsoft DACL May 2018) Similar to a standard ACL, DACLs identifies the accounts that are allowed or denied access to a securable object. When an attempt is made to access a securable object, the system checks the access control entries in the DACL in order. If a matching entry is found, access to the object is granted. Otherwise, access is denied.(Citation: Microsoft Access Control Lists May 2018)

Adversaries can interact with the DACLs using built-in Windows commands, such as `icacls`, `cacls`, `takeown`, and `attrib`, which can grant adversaries higher permissions on specific files and folders. Further, [PowerShell](https://attack.mitre.org/techniques/T1059/001) provides cmdlets that can be used to retrieve or modify file and directory DACLs. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [Accessibility Features](https://attack.mitre.org/techniques/T1546/008), [Boot or Logon Initialization Scripts](https://attack.mitre.org/techniques/T1037), or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](https://attack.mitre.org/techniques/T1574).

Path Interception by PATH Environment Variable - T1574.007

Adversaries may execute their own malicious payloads by hijacking environment variables used to load libraries. The PATH environment variable contains a list of directories (User and System) that the OS searches sequentially through in search of the binary that was called from a script or the command line.

Adversaries can place a malicious program in an earlier entry in the list of directories stored in the PATH environment variable, resulting in the operating system executing the malicious binary rather than the legitimate binary when it searches sequentially through that PATH listing.

For example, on Windows if an adversary places a malicious program named "net.exe" in `C:\example path`, which by default precedes `C:\Windows\system32\net.exe` in the PATH environment variable, when "net" is executed from the command-line the `C:\example path` will be called instead of the system's legitimate executable at `C:\Windows\system32\net.exe`. Some methods of executing a program rely on the PATH environment variable to determine the locations that are searched when the path for the program is not given, such as executing programs from a [Command and Scripting Interpreter](https://attack.mitre.org/techniques/T1059).(Citation: ExpressVPN PATH env Windows 2021)

Adversaries may also directly modify the $PATH variable specifying the directories to be searched. An adversary can modify the `$PATH` variable to point to a directory they have write access. When a program using the $PATH variable is called, the OS searches the specified directory and executes the malicious binary. On macOS, this can also be performed through modifying the $HOME variable. These variables can be modified using the command-line, launchctl, [Unix Shell Configuration Modification](https://attack.mitre.org/techniques/T1546/004), or modifying the `/etc/paths.d` folder contents.(Citation: uptycs Fake POC linux malware 2023)(Citation: nixCraft macOS PATH variables)(Citation: Elastic Rules macOS launchctl 2022)

Path Interception by Search Order Hijacking - T1574.008

Adversaries may execute their own malicious payloads by hijacking the search order used to load other programs. Because some programs do not call other programs using the full path, adversaries may place their own file in the directory where the calling program is located, causing the operating system to launch their malicious software at the request of the calling program.

Search order hijacking occurs when an adversary abuses the order in which Windows searches for programs that are not given a path. Unlike [DLL](https://attack.mitre.org/techniques/T1574/001) search order hijacking, the search order differs depending on the method that is used to execute the program. (Citation: Microsoft CreateProcess) (Citation: Windows NT Command Shell) (Citation: Microsoft WinExec) However, it is common for Windows to search in the directory of the initiating program before searching through the Windows system directory. An adversary who finds a program vulnerable to search order hijacking (i.e., a program that does not specify the path to an

executable) may take advantage of this vulnerability by creating a program named after the improperly specified program and placing it within the initiating program's directory.

For example, "example.exe" runs "cmd.exe" with the command-line argument <code>net user</code>. An adversary may place a program called "net.exe" within the same directory as example.exe, "net.exe" will be run instead of the Windows system utility net. In addition, if an adversary places a program called "net.com" in the same directory as "net.exe", then <code>cmd.exe /C net user</code> will execute "net.com" instead of "net.exe" due to the order of executable extensions defined under PATHEXT. (Citation: Microsoft Environment Property)

Search order hijacking is also a common practice for hijacking DLL loads and is covered in [DLL](https://attack.mitre.org/techniques/T1574/001).

Disable or Modify Linux Audit System - T1562.012

Adversaries may disable or modify the Linux audit system to hide malicious activity and avoid detection. Linux admins use the Linux Audit system to track security-relevant information on a system. The Linux Audit system operates at the kernel-level and maintains event logs on application and system activity such as process, network, file, and login events based on pre-configured rules.

Often referred to as `auditd`, this is the name of the daemon used to write events to disk and is governed by the parameters set in the `audit.conf` configuration file. Two primary ways to configure the log generation rules are through the command line `auditctl` utility and the file `/etc/audit/audit.rules`, containing a sequence of `auditctl` commands loaded at boot time.(Citation: Red Hat System Auditing)(Citation: IzyKnows auditd threat detection 2022)

With root privileges, adversaries may be able to ensure their activity is not logged through disabling the Audit system service, editing the configuration/rule files, or by hooking the Audit system library functions. Using the command line, adversaries can disable the Audit system service through killing processes associated with `auditd` daemon or use `systemctl` to stop the Audit service. Adversaries can also hook Audit system functions to disable logging or modify the rules contained in the `/etc/audit/audit.rules` or `audit.conf` files to ignore malicious activity.(Citation: Trustwave

Disable or Modify Network Device Firewall - T1562.013

Adversaries may disable network device-based firewall mechanisms entirely or add, delete, or modify particular rules in order to bypass controls limiting network usage.

Modifying or disabling a network firewall may enable adversary C2 communications, lateral movement, and/or data exfiltration that would otherwise not be allowed. For example, adversaries may add new network firewall rules to allow access to all internal network subnets without restrictions.(Citation: Exposed Fortinet Fortigate firewall interface leads to LockBit Ransomware)

Adversaries may gain access to the firewall management console via [Valid Accounts](https://attack.mitre.org/techniques/T1078) or by exploiting a vulnerability. In some cases, threat actors may target firewalls that have been exposed to the internet [Exploit Public-Facing Application](https://attack.mitre.org/techniques/T1190).(Citation: CVE-2024-55591 Detail)

Registry Run Keys / Startup Folder - T1060

Adversaries may achieve persistence by adding a program to a startup folder or referencing it with a Registry run key. Adding an entry to the "run keys" in the Registry or startup folder will cause the program referenced to be executed when a user logs in. (Citation: Microsoft Run Key) These programs will be executed under the context of the user and will have the account’s associated

permissions level.

Placing a program within a startup folder will cause that program to execute when a user logs in. There is a startup folder location for individual user accounts as well as a system-wide startup folder that will be checked regardless of which user account logs in.

The startup folder path for the current user is: * <code>C:\Users\[Username]\AppData\Roaming\Microsoft\Windows\Start Menu\Programs\Startup</code> The startup folder path for all users is: * <code>C:\ProgramData\Microsoft\Windows\Start Menu\Programs\StartUp</code>

The following run keys are created by default on Windows systems: * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Run</code> * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce</code> * <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Run</code> * <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce</code>

The <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnceEx</code> is also available but is not created by default on Windows Vista and newer. Registry run key entries can reference programs directly or list them as a dependency. (Citation: Microsoft RunOnceEx APR 2018) For example, it is possible to load a DLL at logon using a "Depend" key with RunOnceEx: <code>reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx\0001\Depend /v 1 /d "C:\temp\evil[.]dll"</code> (Citation: Oddvar Moe RunOnceEx Mar 2018)

The following Registry keys can be used to set startup folder items for persistence: * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code> * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code> * <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code> * <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code>

The following Registry keys can control automatic startup of services during boot: * <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</code> * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</code> * <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServices</code> * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServices</code>

Using policy settings to specify startup programs creates corresponding values in either of two Registry keys: * <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run</code> * <code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run</code>

The Winlogon key controls actions that occur when a user logs on to a computer running Windows 7. Most of these actions are under the control of the operating system, but you can also add custom actions here. The <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Userinit</code> and <code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Shell</code> subkeys can automatically launch programs.

Programs listed in the load value of the registry key <code>HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Windows</code> run when any user logs on.

By default, the multistring BootExecute value of the registry key <code>HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager</code> is set to autocheck autochk *. This value causes Windows, at startup, to check the file-system integrity of the hard disks if the system has been shut down abnormally. Adversaries can add other programs or processes to this registry value which will automatically launch at boot.

Adversaries can use these configuration locations to execute malware, such as remote access tools, to maintain persistence through system reboots. Adversaries may also use [Masquerading](https://attack.mitre.org/techniques/T1036) to make the Registry entries look as if they are associated with legitimate programs.

Component Object Model and Distributed COM - T1175

This technique has been deprecated. Please use [Distributed Component Object Model](https://attack.mitre.org/techniques/T1021/003) and [Component Object Model](https://attack.mitre.org/techniques/T1559/001).

Adversaries may use the Windows Component Object Model (COM) and Distributed Component Object Model (DCOM) for local code execution or to execute on remote systems as part of lateral movement.

COM is a component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces.(Citation: Fireeye Hunting COM June 2019) Through COM, a client object can call methods of server objects, which are typically Dynamic Link Libraries (DLL) or executables (EXE).(Citation: Microsoft COM) DCOM is transparent middleware that extends the functionality of Component Object Model (COM) (Citation: Microsoft COM) beyond a local computer using remote procedure call (RPC) technology.(Citation: Fireeye Hunting COM June 2019)

Permissions to interact with local and remote server COM objects are specified by access control lists (ACL) in the Registry. (Citation: Microsoft COM ACL)(Citation: Microsoft Process Wide Com Keys)(Citation: Microsoft System Wide Com Keys) By default, only Administrators may remotely activate and launch COM objects through DCOM.

Adversaries may abuse COM for local command and/or payload execution. Various COM interfaces are exposed that can be abused to invoke arbitrary execution via a variety of programming languages such as C, C++, Java, and VBScript.(Citation: Microsoft COM) Specific COM objects also exists to directly perform functions beyond code execution, such as creating a [Scheduled Task/Job](https://attack.mitre.org/techniques/T1053), fileless download/execution, and other adversary behaviors such as Privilege Escalation and Persistence.(Citation: Fireeye Hunting COM June 2019)(Citation: ProjectZero File Write EoP Apr 2018)

Adversaries may use DCOM for lateral movement. Through DCOM, adversaries operating in the context of an appropriately privileged user can remotely obtain arbitrary and even direct shellcode execution through Office applications (Citation: Enigma Outlook DCOM Lateral Movement Nov 2017) as well as other Windows objects that contain insecure methods.(Citation: Enigma MMC20 COM Jan 2017)(Citation: Enigma DCOM Lateral Movement Jan 2017) DCOM can also execute macros in existing documents (Citation: Enigma Excel DCOM Sept 2017) and may also invoke [Dynamic Data Exchange](https://attack.mitre.org/techniques/T1173) (DDE) execution directly through a COM created instance of a Microsoft Office application (Citation: Cyberreason DCOM DDE Lateral Movement Nov 2017), bypassing the need for a malicious document.

Deliver Malicious App via Other Means - T1476

Malicious applications are a common attack vector used by adversaries to gain a presence on mobile devices. This technique describes installing a malicious application on targeted mobile devices without involving an authorized app store (e.g., Google Play Store or Apple App Store). Adversaries may wish to avoid placing malicious applications in an authorized app store due to increased potential risk of detection or other reasons. However, mobile devices often are configured to allow application installation only from an authorized app store which would prevent this technique from working.

Delivery methods for the malicious application include:

- [Spearphishing Attachment](https://attack.mitre.org/techniques/T1566/001) - Including the mobile app package as an attachment to an email message.
- [Spearphishing Link](https://attack.mitre.org/techniques/T1566/002) - Including a link to the mobile app package within an email, text message (e.g. SMS, iMessage, Hangouts, WhatsApp, etc.), web site, QR code, or other means.
- Third-Party App Store - Installed from a third-party app store (as opposed to an authorized app store that the device implicitly trusts as part of its default behavior), which may not apply the same level of scrutiny to apps as applied by an authorized app store.(Citation: IBTimes-ThirdParty)(Citation: TrendMicro-RootingMalware)(Citation: TrendMicro-FlappyBird)

Some Android malware comes with functionality to install additional applications, either automatically or when the adversary instructs it to.(Citation: android-trojan-steals-paypal-2fa)

LLMNR/NBT-NS Poisoning and SMB Relay - T1557.001

By responding to LLMNR/NBT-NS network traffic, adversaries may spoof an authoritative source for name resolution to force communication with an adversary controlled system. This activity may be used to collect or relay authentication materials.

Link-Local Multicast Name Resolution (LLMNR) and NetBIOS Name Service (NBT-NS) are Microsoft Windows components that serve as alternate methods of host identification. LLMNR is based upon the Domain Name System (DNS) format and allows hosts on the same local link to perform name resolution for other hosts. NBT-NS identifies systems on a local network by their NetBIOS name. (Citation: Wikipedia LLMNR)(Citation: TechNet NetBIOS)

Adversaries can spoof an authoritative source for name resolution on a victim network by responding to LLMNR (UDP 5355)/NBT-NS (UDP 137) traffic as if they know the identity of the requested host, effectively poisoning the service so that the victims will communicate with the adversary controlled system. If the requested host belongs to a resource that requires identification/authentication, the username and NTLMv2 hash will then be sent to the adversary controlled system. The adversary can then collect the hash information sent over the wire through tools that monitor the ports for traffic or through [Network Sniffing](https://attack.mitre.org/techniques/T1040) and crack the hashes offline through [Brute Force](https://attack.mitre.org/techniques/T1110) to obtain the plaintext passwords.

In some cases where an adversary has access to a system that is in the authentication path between systems or when automated scans that use credentials attempt to authenticate to an adversary controlled system, the NTLMv1/v2 hashes can be intercepted and relayed to access and execute code against a target system. The relay step can happen in conjunction with poisoning but may also

be independent of it.(Citation: byt3bl33d3r NTLM Relaying)(Citation: Secure Ideas SMB Relay) Additionally, adversaries may encapsulate the NTLMv1/v2 hashes into various protocols, such as LDAP, SMB, MSSQL and HTTP, to expand and use multiple services with the valid NTLM response.

Several tools may be used to poison name services within local networks such as NBNSpoof, Metasploit, and [Responder](https://attack.mitre.org/software/S0174).(Citation: GitHub NBNSpoof)(Citation: Rapid7 LLMNR Spoofer)(Citation: GitHub Responder)

Additional Local or Domain Groups - T1098.007

An adversary may add additional local or domain groups to an adversary-controlled account to maintain persistent access to a system or domain.

On Windows, accounts may use the `net localgroup` and `net group` commands to add existing users to local and domain groups.(Citation: Microsoft Net Localgroup)(Citation: Microsoft Net Group) On Linux, adversaries may use the `usermod` command for the same purpose.(Citation: Linux Usermod)

For example, accounts may be added to the local administrators group on Windows devices to maintain elevated privileges. They may also be added to the Remote Desktop Users group, which allows them to leverage [Remote Desktop Protocol](https://attack.mitre.org/techniques/T1021/001) to log into the endpoints in the future.(Citation: Microsoft RDP Logons) Adversaries may also add accounts to VPN user groups to gain future persistence on the network.(Citation: Cyber Security News) On Linux, accounts may be added to the sudoers group, allowing them to persistently leverage [Sudo and Sudo Caching](https://attack.mitre.org/techniques/T1548/003) for elevated privileges.

In Windows environments, machine accounts may also be added to domain groups. This allows the local SYSTEM account to gain privileges on the domain.(Citation: RootDSE AD Detection 2022)

Match Legitimate Name or Location - T1655.001

Adversaries may match or approximate the name or location of legitimate files or resources when naming/placing them. This is done for the sake of evading defenses and observation. This may be done by giving artifacts the name and icon of a legitimate, trusted application (i.e., Settings), or using a package name that matches legitimate, trusted applications (i.e., `com.google.android.gm`).

Adversaries may also use the same icon of the file or application they are trying to mimic.

Disable or Modify System Firewall - T1562.004

Adversaries may disable or modify system firewalls in order to bypass controls limiting network usage. Changes could be disabling the entire mechanism as well as adding, deleting, or modifying particular rules. This can be done numerous ways depending on the operating system, including via command-line, editing Windows Registry keys, and Windows Control Panel.

Modifying or disabling a system firewall may enable adversary C2 communications, lateral movement, and/or data exfiltration that would otherwise not be allowed. For example, adversaries may add a new firewall rule for a well-known protocol (such as RDP) using a non-traditional and potentially less securitized port (i.e. [Non-Standard Port](https://attack.mitre.org/techniques/T1571)).(Citation: change_rdp_port_conti)

Adversaries may also modify host networking settings that indirectly manipulate system firewalls, such as interface bandwidth or network connection request thresholds.(Citation: Huntress BlackCat) Settings related to enabling abuse of various [Remote Services](https://attack.mitre.org/techniques/T1021) may also indirectly modify firewall rules.

In ESXi, firewall rules may be modified directly via the esxcli command line interface (e.g., via `esxcli network firewall set`) or via the vCenter user interface.(Citation: Trellix Rnasomhouse 2024)(Citation: Broadcom ESXi Firewall)

Disable or Modify Cloud Firewall - T1562.007

Adversaries may disable or modify a firewall within a cloud environment to bypass controls that limit access to cloud resources. Cloud firewalls are separate from system firewalls that are described in [Disable or Modify System Firewall](https://attack.mitre.org/techniques/T1562/004).

Cloud environments typically utilize restrictive security groups and firewall rules that only allow network activity from trusted IP addresses via expected ports and protocols. An adversary with appropriate permissions may introduce new firewall rules or policies to allow access into a victim cloud environment and/or move laterally from the cloud control plane to the data plane. For example, an adversary may use a script or utility that creates new ingress rules in existing security groups (or creates new security groups entirely) to allow any TCP/IP connectivity to a cloud-hosted instance.(Citation: Palo Alto Unit 42 Compromised Cloud Compute Credentials 2022) They may also remove networking limitations to support traffic associated with malicious activity (such as cryptomining).(Citation: Expel IO Evil in AWS)(Citation: Palo Alto Unit 42 Compromised Cloud Compute Credentials 2022)

Modifying or disabling a cloud firewall may enable adversary C2 communications, lateral movement, and/or data exfiltration that would otherwise not be allowed. It may also be used to open up resources for [Brute Force](https://attack.mitre.org/techniques/T1110) or [Endpoint Denial of Service](https://attack.mitre.org/techniques/T1499).

Disable or Modify Cloud Logs - T1562.008

An adversary may disable or modify cloud logging capabilities and integrations to limit what data is collected on their activities and avoid detection. Cloud environments allow for collection and analysis of audit and application logs that provide insight into what activities a user does within the environment. If an adversary has sufficient permissions, they can disable or modify logging to avoid detection of their activities.

For example, in AWS an adversary may disable CloudWatch/CloudTrail integrations prior to conducting further malicious activity.(Citation: Following the CloudTrail: Generating strong AWS security signals with Sumo Logic) They may alternatively tamper with logging functionality – for example, by removing any associated SNS topics, disabling multi-region logging, or disabling settings that validate and/or encrypt log files.(Citation: AWS Update Trail)(Citation: Pacu Detection Disruption Module) In Office 365, an adversary may disable logging on mail collection activities for specific users by using the `Set-MailboxAuditBypassAssociation` cmdlet, by disabling M365 Advanced Auditing for the user, or by downgrading the user's license from an Enterprise E5 to an Enterprise E3 license.(Citation: Dark Reading Microsoft 365 Attacks 2021)

SIP and Trust Provider Hijacking - T1553.003

Adversaries may tamper with SIP and trust provider components to mislead the operating system and application control tools when conducting signature validation checks. In user mode, Windows Authenticode (Citation: Microsoft Authenticode) digital signatures are used to verify a file's origin and integrity, variables that may be used to establish trust in signed code (ex: a driver with a valid Microsoft signature may be handled as safe). The signature validation process is handled via the WinVerifyTrust application programming interface (API) function, (Citation: Microsoft WinVerifyTrust) which accepts an inquiry and coordinates with the appropriate trust provider, which is responsible for validating parameters of a signature. (Citation: SpectorOps Subverting Trust Sept 2017)

Because of the varying executable file types and corresponding signature formats, Microsoft created software components called Subject Interface Packages (SIPs) (Citation: EduardosBlog SIPs July 2008) to provide a layer of abstraction between API functions and files. SIPs are responsible for enabling API functions to create, retrieve, calculate, and verify signatures. Unique SIPs exist for most file formats (Executable, PowerShell, Installer, etc., with catalog signing providing a catch-all (Citation: Microsoft Catalog Files and Signatures April 2017)) and are identified by globally unique identifiers (GUIDs). (Citation: SpectorOps Subverting Trust Sept 2017)

Similar to [Code Signing](https://attack.mitre.org/techniques/T1553/002), adversaries may abuse this architecture to subvert trust controls and bypass security policies that allow only legitimately signed code to execute on a system. Adversaries may hijack SIP and trust provider components to mislead operating system and application control tools to classify malicious (or any) code as signed by: (Citation: SpectorOps Subverting Trust Sept 2017)

- Modifying the <code>Dll</code> and <code>FuncName</code> Registry values in <code>HKLM\SOFTWARE[\WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllGetSignedDataMsg{SIP_GUID}</code> that point to the dynamic link library (DLL) providing a SIP's CryptSIPDllGetSignedDataMsg function, which retrieves an encoded digital certificate from a signed file. By pointing to a maliciously-crafted DLL with an exported function that always returns a known good signature value (ex: a Microsoft signature for Portable Executables) rather than the file's real signature, an adversary can apply an acceptable signature value to all files using that SIP (Citation: GitHub SIP POC Sept 2017) (although a hash mismatch will likely occur, invalidating the signature, since the hash returned by the function will not match the value computed from the file).
- Modifying the <code>Dll</code> and <code>FuncName</code> Registry values in <code>HKLM\SOFTWARE\[WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllVerifyIndirectData{SIP_GUID}</code> that point to the DLL providing a SIP's CryptSIPDllVerifyIndirectData function, which validates a file's computed hash against the signed hash value. By pointing to a maliciously-crafted DLL with an exported function that always returns TRUE (indicating that the validation was successful), an adversary can successfully validate any file (with a legitimate signature) using that SIP (Citation: GitHub SIP POC Sept 2017) (with or without hijacking the previously mentioned CryptSIPDllGetSignedDataMsg function). This Registry value could also be redirected to a suitable exported function from an already present DLL, avoiding the requirement to drop and execute a new file on disk.

- Modifying the <code>DLL</code> and <code>Function</code> Registry values in <code>HKLM\SOFTWARE\[WOW6432Node\]Microsoft\Cryptography\Providers\Trust\FinalPolicy\{trust provider GUID}</code> that point to the DLL providing a trust provider's FinalPolicy function, which is where the decoded and parsed signature is checked and the majority of trust decisions are made. Similar to hijacking SIP's CryptSIPDllVerifyIndirectData function, this value can be redirected to a suitable exported function from an already present DLL or a maliciously-crafted DLL (though the implementation of a trust provider is complex).
- **Note:** The above hijacks are also possible without modifying the Registry via [DLL](https://attack.mitre.org/techniques/T1574/001) search order hijacking.

Hijacking SIP or trust provider components can also enable persistent code execution, since these malicious components may be invoked by any application that performs code signing or signature validation. (Citation: SpectorOps Subverting Trust Sept 2017)

Windows Management Instrumentation Event Subscription - T1546.003

Adversaries may establish persistence and elevate privileges by executing malicious content triggered by a Windows Management Instrumentation (WMI) event subscription. WMI can be used to install event filters, providers, consumers, and bindings that execute code when a defined event occurs. Examples of events that may be subscribed to are the wall clock time, user login, or the computer's uptime.(Citation: Mandiant M-Trends 2015)

Adversaries may use the capabilities of WMI to subscribe to an event and execute arbitrary code when that event occurs, providing persistence on a system.(Citation: FireEye WMI SANS

2015)(Citation: FireEye WMI 2015) Adversaries may also compile WMI scripts – using `mofcomp.exe` –into Windows Management Object (MOF) files (.mof extension) that can be used to create a malicious subscription.(Citation: Dell WMI Persistence)(Citation: Microsoft MOF May 2018)

WMI subscription execution is proxied by the WMI Provider Host process (WmiPrvSe.exe) and thus may result in elevated SYSTEM privileges.

Exfiltration to Text Storage Sites - T1567.003

Adversaries may exfiltrate data to text storage sites instead of their primary command and control channel. Text storage sites, such as <code>pastebin[.]com</code>, are commonly used by developers to share code and other information.

Text storage sites are often used to host malicious code for C2 communication (e.g., [Stage Capabilities](https://attack.mitre.org/techniques/T1608)), but adversaries may also use these sites to exfiltrate collected data. Furthermore, paid features and encryption options may allow adversaries to conceal and store data more securely.(Citation: Pastebin EchoSec)

Note: This is distinct from [Exfiltration to Code Repository](https://attack.mitre.org/techniques/T1567/001), which highlight access to code repositories via APIs.

Executable Installer File Permissions Weakness - T1574.005

Adversaries may execute their own malicious payloads by hijacking the binaries used by an installer. These processes may automatically execute specific binaries as part of their functionality or to perform other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself, are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Another variation of this technique can be performed by taking advantage of a weakness that is common in executable, self-extracting installers. During the installation process, it is common for installers to use a subdirectory within the <code>%TEMP%</code> directory to unpack binaries such as DLLs, EXEs, or other payloads. When installers create subdirectories and files they often do not set appropriate permissions to restrict write access, which allows for execution of untrusted code placed in the subdirectories or overwriting of binaries used in the installation process. This behavior is related to and may take advantage of [DLL](https://attack.mitre.org/techniques/T1574/001) search order hijacking.

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. Some installers may also require elevated privileges that will result in privilege escalation when executing adversary controlled code. This behavior is related to [Bypass User Account Control](https://attack.mitre.org/techniques/T1548/002). Several examples of this weakness in existing common installers have been reported to software vendors.(Citation: mozilla_sec_adv_2012) (Citation: Executable Installers are Vulnerable) If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

Path Interception by Unquoted Path - T1574.009

Adversaries may execute their own malicious payloads by hijacking vulnerable file path references. Adversaries can take advantage of paths that lack surrounding quotations by placing an executable in a higher level directory within the path, so that Windows will choose the adversary's executable to launch.

Service paths (Citation: Microsoft CurrentControlSet Services) and shortcut paths may also be vulnerable to path interception if the path has one or more spaces and is not surrounded by quotation marks (e.g., <code>C:\unsafe path with space\program.exe</code> vs. <code>"C:\safe path with space\program.exe"</code>). (Citation: Help eliminate unquoted path) (stored in Windows Registry keys) An adversary can place an executable in a higher level directory of the path, and Windows will resolve that executable instead of the intended executable. For example, if the path in a shortcut is <code>C:\program files\myapp.exe</code>, an adversary may create a program at <code>C:\program.exe</code> that will be run instead of the intended program. (Citation: Windows Unquoted Services) (Citation: Windows Privilege Escalation Guide)

This technique can be used for persistence if executables are called on a regular basis, as well as privilege escalation if intercepted executables are started by a higher privileged process.

The tag is: *misp-galaxy:mitre-attack-pattern="Path Interception by Unquoted Path - T1574.009"*

Image File Execution Options Injection - T1546.012

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by Image File Execution Options (IFEO) debuggers. IFEOs enable a developer to attach a debugger to an application. When a process is created, a debugger present in an application's IFEO will be prepended to the application's name, effectively launching the new process under the debugger (e.g., <code>C:\dbg\ntsd.exe -g notepad.exe</code>). (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can be set directly via the Registry or in Global Flags via the GFlags tool. (Citation: Microsoft GFlags Mar 2017) IFEOs are represented as <code>Debugger</code> values in the Registry under <code>HKLM\SOFTWARE{\Wow6432Node}\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\<executable></code> where <code><executable></code> is the binary on which the debugger is attached. (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can also enable an arbitrary monitor program to be launched when a specified program silently exits (i.e. is prematurely terminated by itself or a second, non kernel-mode process). (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018) Similar to debuggers, silent exit monitoring can be enabled through GFlags and/or by directly modifying IFEO and silent process exit Registry values in <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\</code>. (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018)

Similar to [Accessibility Features](https://attack.mitre.org/techniques/T1546/008), on Windows Vista and later as well as Windows Server 2008 and later, a Registry key may be modified that configures "cmd.exe," or another program that provides backdoor access, as a "debugger" for an accessibility program (ex: utilman.exe). After the Registry is modified, pressing the appropriate key combination at the login screen while at the keyboard or when connected with [Remote Desktop Protocol](https://attack.mitre.org/techniques/T1021/001) will cause the "debugger" program to be executed with SYSTEM privileges. (Citation: Tilbury 2014)

Similar to [Process Injection](https://attack.mitre.org/techniques/T1055), these values may also be abused to obtain privilege escalation by causing a malicious executable to be loaded and run in the context of separate processes on the computer. (Citation: Elastic Process Injection July 2017) Installing IFEO mechanisms may also provide Persistence via continuous triggered invocation.

Malware may also use IFEO to [Impair Defenses](https://attack.mitre.org/techniques/T1562) by registering invalid debuggers that redirect and effectively disable various system and security applications. (Citation: FSecure Hupigon) (Citation: Symantec Ushedix June 2008)

https://attack.mitre.org/techniques/T1011

Network Traffic Capture or Redirection - T1410

An adversary may capture network traffic to and from the device to obtain credentials or other sensitive data, or redirect network traffic to flow through an adversary-controlled gateway to do the same.

A malicious app could register itself as a VPN client on Android or iOS to gain access to network packets. However, on both platforms, the user must grant consent to the app to act as a VPN client, and on iOS the app requires a special entitlement that must be granted by Apple.

Alternatively, if a malicious app is able to escalate operating system privileges, it may be able to use those privileges to gain access to network traffic.

An adversary could redirect network traffic to an adversary-controlled gateway by establishing a VPN connection or by manipulating the device's proxy settings. For example, Skycure (Citation: Skycure-Profiles) describes the ability to redirect network traffic by installing a malicious iOS Configuration Profile.

If applications encrypt their network traffic, sensitive data may not be accessible to an adversary, depending on the point of capture.

App Delivered via Web Download - T1431

The application is downloaded from an arbitrary web site. A link to the application's download URI may be sent in an email or SMS, placed on another web site that the target is likely to view, or sent via other means (such as QR code).

Detection: An EMM/MDM or mobile threat protection solution can identify the presence of unwanted, known insecure, or malicious apps on devices.

Platforms: Android, iOS

The tag is: *misp-galaxy:mitre-attack-pattern="App Delivered via Web Download - T1431"*

Image File Execution Options Injection - T1183

Image File Execution Options (IFEO) enable a developer to attach a debugger to an application. When a process is created, a debugger present in an application's IFEO will be prepended to the application's name, effectively launching the new process under the debugger (e.g., "C:\dbg\ntsd.exe -g notepad.exe"). (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can be set directly via the Registry or in Global Flags via the GFlags tool. (Citation: Microsoft GFlags Mar 2017) IFEOs are represented as <code>Debugger</code> values in the Registry under <code>HKLM\SOFTWARE{\Wow6432Node}\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\<executable></code> where <code><executable></code> is the binary on which the debugger is attached. (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can also enable an arbitrary monitor program to be launched when a specified program silently exits (i.e. is prematurely terminated by itself or a second, non kernel-mode process). (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018) Similar to debuggers, silent exit monitoring can be enabled through GFlags and/or by directly modifying IEFO and silent process exit Registry values in <code>HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\</code>. (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018)

An example where the evil.exe process is started when notepad.exe exits: (Citation: Oddvar Moe IFEO APR 2018)

- <code>reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\notepad.exe" /v GlobalFlag /t REG_DWORD /d 512</code>
- <code>reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\notepad.exe" /v ReportingMode /t REG_DWORD /d 1</code>
- <code>reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\notepad.exe" /v MonitorProcess /d "C:\temp\evil.exe"</code>

Similar to [Process Injection](https://attack.mitre.org/techniques/T1055), these values may be abused to obtain persistence and privilege escalation by causing a malicious executable to be loaded and run in the context of separate processes on the computer. (Citation: Elastic Process Injection July 2017) Installing IFEO mechanisms may also provide Persistence via continuous invocation.

Malware may also use IFEO for Defense Evasion by registering invalid debuggers that redirect and effectively disable various system and security applications. (Citation: FSecure Hupigon) (Citation: Symantec Ushedix June 2008)

SIP and Trust Provider Hijacking - T1198

In user mode, Windows Authenticode (Citation: Microsoft Authenticode) digital signatures are used to verify a file's origin and integrity, variables that may be used to establish trust in signed code (ex: a driver with a valid Microsoft signature may be handled as safe). The signature validation process is handled via the WinVerifyTrust application programming interface (API) function, (Citation: Microsoft WinVerifyTrust) which accepts an inquiry and coordinates with the appropriate trust provider, which is responsible for validating parameters of a signature. (Citation: SpectorOps Subverting Trust Sept 2017)

Because of the varying executable file types and corresponding signature formats, Microsoft created software components called Subject Interface Packages (SIPs) (Citation: EduardosBlog SIPs July 2008) to provide a layer of abstraction between API functions and files. SIPs are responsible for enabling API functions to create, retrieve, calculate, and verify signatures. Unique SIPs exist for most file formats (Executable, PowerShell, Installer, etc., with catalog signing providing a catch-all (Citation: Microsoft Catalog Files and Signatures April 2017)) and are identified by globally unique identifiers (GUIDs). (Citation: SpectorOps Subverting Trust Sept 2017)

Similar to [Code Signing](https://attack.mitre.org/techniques/T1116), adversaries may abuse this architecture to subvert trust controls and bypass security policies that allow only legitimately signed code to execute on a system. Adversaries may hijack SIP and trust provider components to mislead operating system and whitelisting tools to classify malicious (or any) code as signed by: (Citation: SpectorOps Subverting Trust Sept 2017)

- Modifying the <code>Dll</code> and <code>FuncName</code> Registry values in <code>HKLM\SOFTWARE[\WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllGetSignedDataMsg{SIP_GUID}</code> that point to the dynamic link library (DLL) providing a SIP's CryptSIPDllGetSignedDataMsg function, which retrieves an encoded digital certificate from a signed file. By pointing to a maliciously-crafted DLL with an exported function that always returns a known good signature value (ex: a Microsoft signature for Portable Executables) rather than the file's real signature, an adversary can apply an acceptable signature value to all files using that SIP (Citation: GitHub SIP POC Sept 2017) (although a hash mismatch will likely occur, invalidating the signature, since the hash returned by the function

will not match the value computed from the file).

- Modifying the <code>Dll</code> and <code>FuncName</code> Registry values in <code>HKLM\SOFTWARE\[WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllVerifyIndirectData{SIP_GUID}</code> that point to the DLL providing a SIP's CryptSIPDllVerifyIndirectData function, which validates a file's computed hash against the signed hash value. By pointing to a maliciously-crafted DLL with an exported function that always returns TRUE (indicating that the validation was successful), an adversary can successfully validate any file (with a legitimate signature) using that SIP (Citation: GitHub SIP POC Sept 2017) (with or without hijacking the previously mentioned CryptSIPDllGetSignedDataMsg function). This Registry value could also be redirected to a suitable exported function from an already present DLL, avoiding the requirement to drop and execute a new file on disk.
- Modifying the <code>DLL</code> and <code>Function</code> Registry values in <code>HKLM\SOFTWARE\[WOW6432Node\]Microsoft\Cryptography\Providers\Trust\FinalPolicy \{trust provider GUID}</code> that point to the DLL providing a trust provider's FinalPolicy function, which is where the decoded and parsed signature is checked and the majority of trust decisions are made. Similar to hijacking SIP's CryptSIPDllVerifyIndirectData function, this value can be redirected to a suitable exported function from an already present DLL or a maliciously-crafted DLL (though the implementation of a trust provider is complex).
- **Note:** The above hijacks are also possible without modifying the Registry via [DLL Search Order Hijacking](https://attack.mitre.org/techniques/T1038).

Hijacking SIP or trust provider components can also enable persistent code execution, since these malicious components may be invoked by any application that performs code signing or signature validation. (Citation: SpectorOps Subverting Trust Sept 2017)

File and Directory Permissions Modification - T1222

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Modifications may include changing specific access rights, which may require taking ownership of a file or directory and/or elevated permissions depending on the file or directory's existing permissions. This may enable malicious activity such as modifying, replacing, or deleting specific files or directories. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [Accessibility Features](https://attack.mitre.org/techniques/T1546/008), [Boot or Logon Initialization Scripts](https://attack.mitre.org/techniques/T1037), [Unix Shell Configuration Modification](https://attack.mitre.org/techniques/T1546/004), or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](https://attack.mitre.org/techniques/T1574).

Adversaries may also change permissions of symbolic links. For example, malware (particularly ransomware) may modify symbolic links and associated settings to enable access to files from local shortcuts with remote paths.(Citation: new_rust_based_ransomware)(Citation: bad_luck_blackcat)(Citation: falconoverwatch_blackcat_attack)(Citation: blackmatter_blackcat)(Citation: fsutil_behavior)

SSL certificate acquisition for domain - T1337

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](http://attack.mitre.org/matrices/enterprise/pre/) matrix for its replacement. The prior content of this page has been preserved [here](https://attack.mitre.org/versions/v7/techniques/T1337).

Certificates are designed to instill trust. They include information about the key, information about its owner’s identity, and the digital signature of an entity that has verified the certificate’s contents are correct. If the signature is valid, and the person examining the certificate trusts the signer, then they know they can use that key to communicate with its owner. Acquiring a certificate for a domain name similar to one that is expected to be trusted may allow an adversary to trick a user in to trusting the domain (e.g., vvachovia instead of [Wachovia](https://www.wellsfargo.com/about/corporate/wachovia) — homoglyphs). Transfer Data to Cloud Account - T1537

Adversaries may exfiltrate data by transferring the data, including through sharing/syncing and creating backups of cloud environments, to another cloud account they control on the same service.

A defender who is monitoring for large transfers to outside the cloud environment through normal file transfers or over command and control channels may not be watching for data transfers to another account within the same cloud provider. Such transfers may utilize existing cloud provider APIs and the internal address space of the cloud provider to blend into normal traffic or avoid data transfers over external network interfaces.(Citation: TLDRSec AWS Attacks)

Adversaries may also use cloud-native mechanisms to share victim data with adversary-controlled cloud accounts, such as creating anonymous file sharing links or, in Azure, a shared access signature (SAS) URI.(Citation: Microsoft Azure Storage Shared Access Signature)

Incidents have been observed where adversaries have created backups of cloud instances and transferred them to separate accounts.(Citation: DOJ GRU Indictment Jul 2018)

Domain or Tenant Policy Modification - T1484

Adversaries may modify the configuration settings of a domain or identity tenant to evade defenses and/or escalate privileges in centrally managed environments. Such services provide a centralized means of managing identity resources such as devices and accounts, and often include configuration settings that may apply between domains or tenants such as trust relationships, identity syncing, or identity federation.

Modifications to domain or tenant settings may include altering domain Group Policy Objects (GPOs) in Microsoft Active Directory (AD) or changing trust settings for domains, including federation trusts relationships between domains or tenants.

With sufficient permissions, adversaries can modify domain or tenant policy settings. Since configuration settings for these services apply to a large number of identity resources, there are a great number of potential attacks malicious outcomes that can stem from this abuse. Examples of such abuse include:

- modifying GPOs to push a malicious [Scheduled Task](https://attack.mitre.org/techniques/T1053/005) to computers throughout the domain environment(Citation: ADSecurity GPO Persistence 2016)(Citation: Wald0 Guide to GPOs)(Citation: Harmj0y Abusing GPO Permissions)
- modifying domain trusts to include an adversary-controlled domain, allowing adversaries to forge access tokens that will subsequently be accepted by victim domain resources(Citation: Microsoft - Customer Guidance on Recent Nation-State Cyber Attacks)
- changing configuration settings within the AD environment to implement a [Rogue Domain Controller](https://attack.mitre.org/techniques/T1207).
- adding new, adversary-controlled federated identity providers to identity tenants, allowing adversaries to authenticate as any user managed by the victim tenant (Citation: Okta Cross-Tenant Impersonation 2023)

Adversaries may temporarily modify domain or tenant policy, carry out a malicious action(s), and

then revert the change to remove suspicious indicators.

The tag is: *misp-galaxy:mitre-attack-pattern="Domain or Tenant Policy Modification - T1484"*

Boot or Logon Autostart Execution - T1547

Adversaries may configure system settings to automatically execute a program during system boot or logon to maintain persistence or gain higher-level privileges on compromised systems. Operating systems may have mechanisms for automatically running a program on system boot or account logon.(Citation: Microsoft Run Key)(Citation: MSDN Authentication Packages)(Citation: Microsoft TimeProvider)(Citation: Cylance Reg Persistence Sept 2013)(Citation: Linux Kernel Programming) These mechanisms may include automatically executing programs that are placed in specially designated directories or are referenced by repositories that store configuration information, such as the Windows Registry. An adversary may achieve the same goal by modifying or extending features of the kernel.

Since some boot or logon autostart programs run with higher privileges, an adversary may leverage these to elevate privileges.

Steal or Forge Authentication Certificates - T1649

Adversaries may steal or forge certificates used for authentication to access remote systems or resources. Digital certificates are often used to sign and encrypt messages and/or files. Certificates are also used as authentication material. For example, Entra ID device certificates and Active Directory Certificate Services (AD CS) certificates bind to an identity and can be used as credentials for domain accounts.(Citation: O365 Blog Azure AD Device IDs)(Citation: Microsoft AD CS Overview)

Authentication certificates can be both stolen and forged. For example, AD CS certificates can be stolen from encrypted storage (in the Registry or files)(Citation: APT29 Deep Look at Credential Roaming), misplaced certificate files (i.e. [Unsecured Credentials](https://attack.mitre.org/techniques/T1552)), or directly from the Windows certificate store via various crypto APIs.(Citation: SpecterOps Certified Pre Owned)(Citation: GitHub CertStealer)(Citation: GitHub GhostPack Certificates) With appropriate enrollment rights, users and/or machines within a domain can also request and/or manually renew certificates from enterprise certificate authorities (CA). This enrollment process defines various settings and permissions associated with the certificate. Of note, the certificate's extended key usage (EKU) values define signing, encryption, and authentication use cases, while the certificate's subject alternative name (SAN) values define the certificate owner's

alternate names.(Citation: Medium Certified Pre Owned)

Abusing certificates for authentication credentials may enable other behaviors such as [Lateral Movement](https://attack.mitre.org/tactics/TA0008). Certificate-related misconfigurations may also enable opportunities for [Privilege Escalation](https://attack.mitre.org/tactics/TA0004), by way of allowing users to impersonate or assume privileged accounts or permissions via the identities (SANs) associated with a certificate. These abuses may also enable [Persistence](https://attack.mitre.org/tactics/TA0003) via stealing or forging certificates that can be used as [Valid Accounts](https://attack.mitre.org/techniques/T1078) for the duration of the certificate's validity, despite user password resets. Authentication certificates can also be stolen and forged for machine accounts.

Adversaries who have access to root (or subordinate) CA certificate private keys (or mechanisms protecting/managing these keys) may also establish [Persistence](https://attack.mitre.org/tactics/TA0003) by forging arbitrary authentication certificates for the victim domain (known as "golden" certificates).(Citation: Medium Certified Pre Owned) Adversaries may also target certificates and related services in order to access other forms of credentials, such as [Golden Ticket](https://attack.mitre.org/techniques/T1558/001) ticket-granting tickets (TGT) or NTLM plaintext.(Citation: Medium Certified Pre Owned)

Install Insecure or Malicious Configuration - T1478

An adversary could attempt to install insecure or malicious configuration settings on the mobile device, through means such as phishing emails or text messages either directly containing the configuration settings as an attachment, or containing a web link to the configuration settings. The device user may be tricked into installing the configuration settings through social engineering techniques (Citation: Symantec-iOSProfile).

For example, an unwanted Certification Authority (CA) certificate could be placed in the device's trusted certificate store, increasing the device's susceptibility to adversary-in-the-middle network attacks seeking to eavesdrop on or manipulate the device's network communication ([Eavesdrop on Insecure Network Communication](https://attack.mitre.org/techniques/T1439) and [Manipulate Device Communication](https://attack.mitre.org/techniques/T1463)).

On iOS, malicious Configuration Profiles could contain unwanted Certification Authority (CA) certificates or other insecure settings such as unwanted proxy server or VPN settings to route the device's network traffic through an adversary's system. The device could also potentially be enrolled into a malicious Mobile Device Management (MDM) system (Citation: Talos-MDM).

Steal or Forge Kerberos Tickets - T1558

Adversaries may attempt to subvert Kerberos authentication by stealing or forging Kerberos tickets to enable [Pass the Ticket](https://attack.mitre.org/techniques/T1550/003). Kerberos is an authentication protocol widely used in modern Windows domain environments. In Kerberos environments, referred to as "realms", there are three basic participants: client, service, and Key Distribution Center (KDC).(Citation: ADSecurity Kerberos Ring Decoder) Clients request access to a service and through the exchange of Kerberos tickets, originating from KDC, they are granted access after having successfully authenticated. The KDC is responsible for both authentication and ticket granting. Adversaries may attempt to abuse Kerberos by stealing tickets or forging tickets to

enable unauthorized access.

On Windows, the built-in <code>klist</code> utility can be used to list and analyze cached Kerberos tickets.(Citation: Microsoft Klist)

LLMNR/NBT-NS Poisoning and Relay - T1171

Link-Local Multicast Name Resolution (LLMNR) and NetBIOS Name Service (NBT-NS) are Microsoft Windows components that serve as alternate methods of host identification. LLMNR is based upon the Domain Name System (DNS) format and allows hosts on the same local link to perform name resolution for other hosts. NBT-NS identifies systems on a local network by their NetBIOS name. (Citation: Wikipedia LLMNR) (Citation: TechNet NetBIOS)

Adversaries can spoof an authoritative source for name resolution on a victim network by responding to LLMNR (UDP 5355)/NBT-NS (UDP 137) traffic as if they know the identity of the requested host, effectively poisoning the service so that the victims will communicate with the adversary controlled system. If the requested host belongs to a resource that requires identification/authentication, the username and NTLMv2 hash will then be sent to the adversary controlled system. The adversary can then collect the hash information sent over the wire through tools that monitor the ports for traffic or through [Network Sniffing](https://attack.mitre.org/techniques/T1040) and crack the hashes offline through [Brute Force](https://attack.mitre.org/techniques/T1110) to obtain the plaintext passwords. In some cases where an adversary has access to a system that is in the authentication path between systems or when automated scans that use credentials attempt to authenticate to an adversary controlled system, the NTLMv2 hashes can be intercepted and relayed to access and execute code against a target system. The relay step can happen in conjunction with poisoning but may also be independent of it. (Citation: byt3bl33d3r NTLM Relaying)(Citation: Secure Ideas SMB Relay)

Several tools exist that can be used to poison name services within local networks such as NBNSpoof, Metasploit, and [Responder](https://attack.mitre.org/software/S0174). (Citation: GitHub NBNSpoof) (Citation: Rapid7 LLMNR Spoofer) (Citation: GitHub Responder)

Multi-Factor Authentication Request Generation - T1621

Adversaries may attempt to bypass multi-factor authentication (MFA) mechanisms and gain access to accounts by generating MFA requests sent to users.

Adversaries in possession of credentials to [Valid Accounts](https://attack.mitre.org/techniques/T1078) may be unable to complete the login process if they lack access to the 2FA or MFA mechanisms required as an additional credential and security control. To circumvent this, adversaries may abuse the automatic generation of push notifications to MFA services such as Duo Push, Microsoft Authenticator, Okta, or similar services to have the user grant access to their account. If adversaries lack credentials to victim accounts, they may also abuse automatic push notification generation when this option is configured for self-service password reset (SSPR).(Citation: Obsidian SSPR Abuse 2023)

In some cases, adversaries may continuously repeat login attempts in order to bombard users with MFA push notifications, SMS messages, and phone calls, potentially resulting in the user finally accepting the authentication request in response to “MFA fatigue.”(Citation: Russian 2FA Push Annoyance - Cimpanu)(Citation: MFA Fatigue Attacks - PortSwigger)(Citation: Suspected Russian Activity Targeting Government and Business Entities Around the Globe)

Protocol or Service Impersonation - T1001.003

Adversaries may impersonate legitimate protocols or web service traffic to disguise command and control activity and thwart analysis efforts. By impersonating legitimate protocols or web services, adversaries can make their command and control traffic blend in with legitimate network traffic.

Adversaries may impersonate a fake SSL/TLS handshake to make it look like subsequent traffic is SSL/TLS encrypted, potentially interfering with some security tooling, or to make the traffic look like it is related with a trusted entity.

Adversaries may also leverage legitimate protocols to impersonate expected web traffic or trusted services. For example, adversaries may manipulate HTTP headers, URI endpoints, SSL certificates, and transmitted data to disguise C2 communications or mimic legitimate services such as Gmail, Google Drive, and Yahoo Messenger.(Citation: ESET Okrum July 2019)(Citation: Malleable-C2-U42)

Clear Windows Event Logs - T1070.001

Adversaries may clear Windows Event Logs to hide the activity of an intrusion. Windows Event Logs are a record of a computer's alerts and notifications. There are three system-defined sources of events: System, Application, and Security, with five event types: Error, Warning, Information, Success Audit, and Failure Audit.

With administrator privileges, the event logs can be cleared with the following utility commands:

- <code>wevtutil cl system</code>
- <code>wevtutil cl application</code>
- <code>wevtutil cl security</code>

These logs may also be cleared through other mechanisms, such as the event viewer GUI or [PowerShell](https://attack.mitre.org/techniques/T1059/001). For example, adversaries may use the PowerShell command <code>Remove-EventLog -LogName Security</code> to delete the Security EventLog and after reboot, disable future logging. Note: events may still be generated and logged in the .evtx file between the time the command is run and the reboot.(Citation: disable_win_evt_logging)

Adversaries may also attempt to clear logs by directly deleting the stored log files within `C:\Windows\System32\winevt\logs\`.

The tag is: *misp-galaxy:mitre-attack-pattern="Clear Windows Event Logs - T1070.001"*

Network Share Connection Removal - T1070.005

Adversaries may remove share connections that are no longer useful in order to clean up traces of their operation. Windows shared drive and [SMB/Windows Admin Shares](https://attack.mitre.org/techniques/T1021/002) connections can be removed when no longer needed. [Net](https://attack.mitre.org/software/S0039) is an example utility that can be used to remove network share connections with the <code>net use \\system\share /delete</code> command.

(Citation: Technet Net Use)

Distributed Component Object Model - T1021.003

Adversaries may use [Valid Accounts](https://attack.mitre.org/techniques/T1078) to interact with remote machines by taking advantage of Distributed Component Object Model (DCOM). The adversary may then perform actions as the logged-on user.

The Windows Component Object Model (COM) is a component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces. Through COM, a client object can call methods of server objects, which are typically Dynamic Link Libraries (DLL) or executables (EXE). Distributed COM (DCOM) is transparent middleware that extends the functionality of COM beyond a local computer using remote procedure call (RPC) technology.(Citation: Fireeye Hunting COM June 2019)(Citation: Microsoft COM)

Permissions to interact with local and remote server COM objects are specified by access control lists (ACL) in the Registry.(Citation: Microsoft Process Wide Com Keys) By default, only Administrators may remotely activate and launch COM objects through DCOM.(Citation: Microsoft COM ACL)

Through DCOM, adversaries operating in the context of an appropriately privileged user can remotely obtain arbitrary and even direct shellcode execution through Office applications(Citation: Enigma Outlook DCOM Lateral Movement Nov 2017) as well as other Windows objects that contain insecure methods.(Citation: Enigma MMC20 COM Jan 2017)(Citation: Enigma DCOM Lateral Movement Jan 2017) DCOM can also execute macros in existing documents(Citation: Enigma Excel DCOM Sept 2017) and may also invoke [Dynamic Data Exchange](https://attack.mitre.org/techniques/T1559/002) (DDE) execution directly through a COM created instance of a Microsoft Office application(Citation: Cyberreason DCOM DDE Lateral Movement Nov 2017), bypassing the need for a malicious document. DCOM can be used as a method of remotely interacting with [Windows Management Instrumentation](https://attack.mitre.org/techniques/T1047). (Citation: MSDN WMI)

Direct Cloud VM Connections - T1021.008

Adversaries may leverage [Valid Accounts](https://attack.mitre.org/techniques/T1078) to log directly into accessible cloud hosted compute infrastructure through cloud native methods. Many cloud providers offer interactive connections to virtual infrastructure that can be accessed through the [Cloud API](https://attack.mitre.org/techniques/T1059/009), such as Azure Serial Console(Citation: Azure Serial Console), AWS EC2 Instance Connect(Citation: EC2 Instance Connect)(Citation: lucr-3: Getting SaaS-y in the cloud), and AWS System Manager.(Citation: AWS System Manager).

Methods of authentication for these connections can include passwords, application access tokens, or SSH keys. These cloud native methods may, by default, allow for privileged access on the host with SYSTEM or root level access.

Adversaries may utilize these cloud native methods to directly access virtual infrastructure and pivot through an environment.(Citation: SIM Swapping and Abuse of the Microsoft Azure Serial Console) These connections typically provide direct console access to the VM rather than the execution of scripts (i.e., [Cloud Administration Command](https://attack.mitre.org/techniques/T1651)).

The tag is: *misp-galaxy:mitre-attack-pattern="Direct Cloud VM Connections - T1021.008"*

Network Device Configuration Dump - T1602.002

Adversaries may access network configuration files to collect sensitive data about the device and the network. The network configuration is a file containing parameters that determine the operation of the device. The device typically stores an in-memory copy of the configuration while operating, and a separate configuration on non-volatile storage to load after device reset. Adversaries can inspect the configuration files to reveal information about the target network and its layout, the network device and its software, or identifying legitimate accounts and credentials for later use.

Adversaries can use common management tools and protocols, such as Simple Network Management Protocol (SNMP) and Smart Install (SMI), to access network configuration files.(Citation: US-CERT TA18-106A Network Infrastructure Devices 2018)(Citation: Cisco Blog Legacy Device Attacks) These tools may be used to query specific data from a configuration repository or configure the device to export the configuration for later analysis.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Device Configuration Dump - T1602.002"*

Malicious Copy and Paste - T1204.004

An adversary may rely upon a user copying and pasting code in order to gain execution. Users may be subjected to social engineering to get them to copy and paste code directly into a [Command and Scripting Interpreter](https://attack.mitre.org/techniques/T1059). One such strategy is "ClickFix," in which adversaries present users with seemingly helpful solutions—such as prompts to fix errors or complete CAPTCHAs—that instead instruct the user to copy and paste malicious code.

Malicious websites, such as those used in [Drive-by Compromise](https://attack.mitre.org/techniques/T1189), may present fake error messages or CAPTCHA prompts that instruct users to open a terminal or the Windows Run Dialog box and execute an arbitrary command. These commands may be obfuscated using encoding or other techniques to conceal malicious intent. Once executed, the adversary will typically be able to establish a foothold on the victim's machine.(Citation: CloudSEK Lumma Stealer 2024)(Citation: Sekoia ClickFake 2025)(Citation: Reliaquest CAPTCHA 2024)(Citation: AhnLab LummaC2 2025)

Adversaries may also leverage phishing emails for this purpose. When a user attempts to open an attachment, they may be presented with a fake error and offered a malicious command to paste as a solution, consistent with the "ClickFix" strategy.(Citation: Proofpoint ClickFix 2024)(Citation: AhnLab Malicioys Copy Paste 2024)

Tricking a user into executing a command themselves may help to bypass email filtering, browser sandboxing, or other mitigations designed to protect users against malicious downloaded files.

Indicator Removal from Tools - T1027.005

Adversaries may remove indicators from tools if they believe their malicious tool was detected, quarantined, or otherwise curtailed. They can modify the tool by removing the indicator and using the updated version that is no longer detected by the target's defensive systems or subsequent targets that may use similar systems.

A good example of this is when malware is detected with a file signature and quarantined by anti-virus software. An adversary who can determine that the malware was quarantined because of its file signature may modify the file to explicitly avoid that signature, and then re-use the malware.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal from Tools - T1027.005"*

Table 8079. Table References

Links
https://attack.mitre.org/techniques/T1027/005

Additional Email Delegate Permissions - T1098.002

Adversaries may grant additional permission levels to maintain persistent access to an adversary-controlled email account.

For example, the <code>Add-MailboxPermission</code> [PowerShell](https://attack.mitre.org/techniques/T1059/001) cmdlet, available in on-premises Exchange and in the cloud-based service Office 365, adds permissions to a mailbox.(Citation: Microsoft - Add-MailboxPermission)(Citation: FireEye APT35 2018)(Citation: Crowdstrike Hiding in Plain Sight 2018) In Google Workspace, delegation can be enabled via the Google Admin console and users can delegate accounts via their Gmail settings.(Citation: Gmail Delegation)(Citation: Google Ensuring Your Information is Safe)

Adversaries may also assign mailbox folder permissions through individual folder permissions or roles. In Office 365 environments, adversaries may assign the Default or Anonymous user permissions or roles to the Top of Information Store (root), Inbox, or other mailbox folders. By assigning one or both user permissions to a folder, the adversary can utilize any other account in the tenant to maintain persistence to the target user's mail folders.(Citation: Mandiant Defend UNC2452 White Paper)

This may be used in persistent threat incidents as well as BEC (Business Email Compromise) incidents where an adversary can add [Additional Cloud Roles](https://attack.mitre.org/techniques/T1098/003) to the accounts they wish to compromise. This may further enable use of additional techniques for gaining access to systems. For example, compromised business accounts are often used to send messages to other accounts in the network of the target business while creating inbox rules (ex: [Internal Spearphishing](https://attack.mitre.org/techniques/T1534)), so the messages evade spam/phishing detection mechanisms.(Citation: Bienstock, D. - Defending O365 - 2019)

The tag is: *misp-galaxy:mitre-attack-pattern="Additional Email Delegate Permissions - T1098.002"*

Masquerade Task or Service - T1036.004

Adversaries may attempt to manipulate the name of a task or service to make it appear legitimate or benign. Tasks/services executed by the Task Scheduler or systemd will typically be given a name and/or description.(Citation: TechNet Schtasks)(Citation: Systemd Service Units) Windows services will have a service name as well as a display name. Many benign tasks and services exist that have commonly associated names. Adversaries may give tasks or services names that are similar or identical to those of legitimate ones.

Tasks or services contain other fields, such as a description, that adversaries may attempt to make appear legitimate.(Citation: Palo Alto Shamoon Nov 2016)(Citation: Fysbis Dr Web Analysis)

The tag is: *misp-galaxy:mitre-attack-pattern="Masquerade Task or Service - T1036.004"*

https://attack.mitre.org/techniques/T1560/003

Additional Container Cluster Roles - T1098.006

An adversary may add additional roles or permissions to an adversary-controlled user or service account to maintain persistent access to a container orchestration system. For example, an adversary with sufficient permissions may create a RoleBinding or a ClusterRoleBinding to bind a Role or ClusterRole to a Kubernetes account.(Citation: Kubernetes RBAC)(Citation: Aquasec Kubernetes Attack 2023) Where attribute-based access control (ABAC) is in use, an adversary with sufficient permissions may modify a Kubernetes ABAC policy to give the target account additional permissions.(Citation: Kuberentes ABAC)

This account modification may immediately follow [Create Account](https://attack.mitre.org/techniques/T1136) or other malicious account activity. Adversaries may also modify existing [Valid Accounts](https://attack.mitre.org/techniques/T1078) that they have compromised.

Note that where container orchestration systems are deployed in cloud environments, as with Google Kubernetes Engine, Amazon Elastic Kubernetes Service, and Azure Kubernetes Service, cloud-based role-based access control (RBAC) assignments or ABAC policies can often be used in place of or in addition to local permission assignments.(Citation: Google Cloud Kubernetes IAM)(Citation: AWS EKS IAM Roles for Service Accounts)(Citation: Microsoft Azure Kubernetes Service Service Accounts) In these cases, this technique may be used in conjunction with [Additional Cloud Roles](https://attack.mitre.org/techniques/T1098/003).

The tag is: *misp-galaxy:mitre-attack-pattern="Additional Container Cluster Roles - T1098.006"*

Extra Window Memory Injection - T1055.011

Adversaries may inject malicious code into process via Extra Window Memory (EWM) in order to evade process-based defenses as well as possibly elevate privileges. EWM injection is a method of executing arbitrary code in the address space of a separate live process.

Before creating a window, graphical Windows-based processes must prescribe to or register a windows class, which stipulate appearance and behavior (via windows procedures, which are functions that handle input/output of data).(Citation: Microsoft Window Classes) Registration of

new windows classes can include a request for up to 40 bytes of EWM to be appended to the allocated memory of each instance of that class. This EWM is intended to store data specific to that window and has specific application programming interface (API) functions to set and get its value. (Citation: Microsoft GetWindowLong function) (Citation: Microsoft SetWindowLong function)

Although small, the EWM is large enough to store a 32-bit pointer and is often used to point to a windows procedure. Malware may possibly utilize this memory location in part of an attack chain that includes writing code to shared sections of the process's memory, placing a pointer to the code in EWM, then invoking execution by returning execution control to the address in the process's EWM.

Execution granted through EWM injection may allow access to both the target process's memory and possibly elevated privileges. Writing payloads to shared sections also avoids the use of highly monitored API calls such as <code>WriteProcessMemory</code> and <code>CreateRemoteThread</code>.(Citation: Elastic Process Injection July 2017) More sophisticated malware samples may also potentially bypass protection mechanisms such as data execution prevention (DEP) by triggering a combination of windows procedures and other system functions that will rewrite the malicious payload inside an executable portion of the target process. (Citation: MalwareTech Power Loader Aug 2013) (Citation: WeLiveSecurity Gapz and Redyms Mar 2013)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via EWM injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Extra Window Memory Injection - T1055.011"*

Customer Relationship Management Software - T1213.004

Adversaries may leverage Customer Relationship Management (CRM) software to mine valuable

information. CRM software is used to assist organizations in tracking and managing customer interactions, as well as storing customer data.

Once adversaries gain access to a victim organization, they may mine CRM software for customer data. This may include personally identifiable information (PII) such as full names, emails, phone numbers, and addresses, as well as additional details such as purchase histories and IT support interactions. By collecting this data, an adversary may be able to send personalized [Phishing](https://attack.mitre.org/techniques/T1566) emails, engage in SIM swapping, or otherwise target the organization's customers in ways that enable financial gain or the compromise of additional organizations.(Citation: Bleeping Computer US Cellular Hack 2022)(Citation: Bleeping Computer Mint Mobile Hack 2021)(Citation: Bleeping Computer Bank Hack 2020)

CRM software may be hosted on-premises or in the cloud. Information stored in these solutions may vary based on the specific instance or environment. Examples of CRM software include Microsoft Dynamics 365, Salesforce, Zoho, Zendesk, and HubSpot.

The tag is: *misp-galaxy:mitre-attack-pattern="Customer Relationship Management Software - T1213.004"*

Create Process with Token - T1134.002

Adversaries may create a new process with an existing token to escalate privileges and bypass access controls. Processes can be created with the token and resulting security context of another user using features such as <code>CreateProcessWithTokenW</code> and <code>runas</code>.(Citation: Microsoft RunAs)

Creating processes with a token not associated with the current user may require the credentials of the target user, specific privileges to impersonate that user, or access to the token to be used. For example, the token could be duplicated via [Token Impersonation/Theft](https://attack.mitre.org/techniques/T1134/001) or created via [Make and Impersonate Token](https://attack.mitre.org/techniques/T1134/003) before being used to create a process.

While this technique is distinct from [Token Impersonation/Theft](https://attack.mitre.org/techniques/T1134/001), the techniques can be used in conjunction where a token is duplicated and then used to create a new process.

The tag is: *misp-galaxy:mitre-attack-pattern="Create Process with Token - T1134.002"*

Code Signing Policy Modification - T1632.001

Adversaries may modify code signing policies to enable execution of applications signed with unofficial or unknown keys. Code signing provides a level of authenticity on an app from a developer, guaranteeing that the program has not been tampered with and comes from an official source. Security controls can include enforcement mechanisms to ensure that only valid, signed code can be run on a device.

Mobile devices generally enable these security controls by default, such as preventing the installation of unknown applications on Android. Adversaries may modify these policies in a number of ways, including [Input Injection](https://attack.mitre.org/techniques/T1516) or malicious configuration profiles.

The tag is: *misp-galaxy:mitre-attack-pattern="Code Signing Policy Modification - T1632.001"*

Table 8087. Table References

System Runtime API Hijacking - T1625.001

Adversaries may execute their own malicious payloads by hijacking the way an operating system runs applications. Hijacking execution flow can be for the purposes of persistence since this hijacked execution may reoccur at later points in time.

On Android, adversaries may overwrite the standard OS API library with a malicious alternative to hook into core functions to achieve persistence. By doing this, the adversary's code will be executed every time the overwritten API function is called by an app on the infected device.

The tag is: *misp-galaxy:mitre-attack-pattern="System Runtime API Hijacking - T1625.001"*

Table 8088. Table References

Links
https://attack.mitre.org/techniques/T1625/001
https://pages.nist.gov/mobile-threat-catalogue/application-threats/APP-27.html

Disable or Modify Tools - T1562.001

Adversaries may modify and/or disable security tools to avoid possible detection of their malware/tools and activities. This may take many forms, such as killing security software processes or services, modifying / deleting Registry keys or configuration files so that tools do not operate properly, or other methods to interfere with security tools scanning or reporting information. Adversaries may also disable updates to prevent the latest security patches from reaching tools on victim systems.(Citation: SCADAfence_ransomware)

Adversaries may trigger a denial-of-service attack via legitimate system processes. It has been previously observed that the Windows Time Travel Debugging (TTD) monitor driver can be used to initiate a debugging session for a security tool (e.g., an EDR) and render the tool non-functional. By hooking the debugger into the EDR process, all child processes from the EDR will be automatically suspended. The attacker can terminate any EDR helper processes (unprotected by Windows Protected Process Light) by abusing the Process Explorer driver. In combination this will halt any attempt to restart services and cause the tool to crash.(Citation: Cocomazzi FIN7 Reboot)

Adversaries may also tamper with artifacts deployed and utilized by security tools. Security tools may make dynamic changes to system components in order to maintain visibility into specific events. For example, security products may load their own modules and/or modify those loaded by processes to facilitate data collection. Similar to [Indicator Blocking](https://attack.mitre.org/techniques/T1562/006), adversaries may unhook or otherwise modify these features added by tools (especially those that exist in userland or are otherwise potentially accessible to adversaries) to avoid detection.(Citation: OutFlank System Calls)(Citation: MDSec System Calls) For example, adversaries may abuse the Windows process mitigation policy to block certain endpoint detection and response (EDR) products from loading their user-mode code via DLLs. By spawning a process with the PROCESS_CREATION_MITIGATION_POLICY_BLOCK_NON_MICROSOFT_BINARIES_ALWAYS_ON attribute using API calls like UpdateProcThreadAttribute, adversaries may evade detection by endpoint security solutions that rely on DLLs that are not signed by Microsoft. Alternatively, they may add new directories to an EDR tool's exclusion list, enabling them to hide malicious files via [File/Path Exclusions](https://attack.mitre.org/techniques/T1564/012).(Citation: BlackBerry WhisperGate 2022)(Citation: Google Cloud Threat Intelligence FIN13 2021)

Adversaries may also focus on specific applications such as Sysmon. For example, the "Start" and "Enable" values in <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\WMI\Autologger\EventLog-Microsoft-Windows-Sysmon-Operational</code> may be modified to tamper with and potentially disable Sysmon logging.(Citation: disable_win_evt_logging)

On network devices, adversaries may attempt to skip digital signature verification checks by altering startup configuration files and effectively disabling firmware verification that typically occurs at boot.(Citation: Fortinet Zero-Day and Custom Malware Used by Suspected Chinese Actor in Espionage Operation)(Citation: Analysis of FG-IR-22-369)

In cloud environments, tools disabled by adversaries may include cloud monitoring agents that report back to services such as AWS CloudWatch or Google Cloud Monitor.

Furthermore, although defensive tools may have anti-tampering mechanisms, adversaries may

abuse tools such as legitimate rootkit removal kits to impair and/or disable these tools.(Citation: chasing_avaddon_ransomware)(Citation: dharma_ransomware)(Citation: demystifying_ryuk)(Citation: doppelpaymer_crowdstrike) For example, adversaries have used tools such as GMER to find and shut down hidden processes and antivirus software on infected systems.(Citation: demystifying_ryuk)

Additionally, adversaries may exploit legitimate drivers from anti-virus software to gain access to kernel space (i.e. [Exploitation for Privilege Escalation](https://attack.mitre.org/techniques/T1068)), which may lead to bypassing anti-tampering features.(Citation: avoslocker_ransomware)

Compromise Software Supply Chain - T1195.002

Adversaries may manipulate application software prior to receipt by a final consumer for the purpose of data or system compromise. Supply chain compromise of software can take place in a number of ways, including manipulation of the application source code, manipulation of the update/distribution mechanism for that software, or replacing compiled releases with a modified

version.

Targeting may be specific to a desired victim set or may be distributed to a broad set of consumers but only move on to additional tactics on specific victims.(Citation: Avast CCleaner3 2018)(Citation: Command Five SK 2011)

Make and Impersonate Token - T1134.003

Adversaries may make new tokens and impersonate users to escalate privileges and bypass access controls. For example, if an adversary has a username and password but the user is not logged onto the system the adversary can then create a logon session for the user using the `LogonUser` function.(Citation: LogonUserW function) The function will return a copy of the new session's access token and the adversary can use `SetThreadToken` to assign the token to a thread.

This behavior is distinct from [Token Impersonation/Theft](https://attack.mitre.org/techniques/T1134/001) in that this refers to creating a new user token instead of stealing or duplicating an existing one.

The tag is: *misp-galaxy:mitre-attack-pattern="Make and Impersonate Token - T1134.003"*

Compromise Hardware Supply Chain - T1195.003

Adversaries may manipulate hardware components in products prior to receipt by a final consumer for the purpose of data or system compromise. By modifying hardware or firmware in the supply chain, adversaries can insert a backdoor into consumer networks that may be difficult to detect and give the adversary a high degree of control over the system. Hardware backdoors may be inserted into various devices, such as servers, workstations, network infrastructure, or peripherals.

The tag is: *misp-galaxy:mitre-attack-pattern="Compromise Hardware Supply Chain - T1195.003"*

Table 8092. Table References

Links
https://attack.mitre.org/techniques/T1195/003

Change Default File Association - T1546.001

Adversaries may establish persistence by executing malicious content triggered by a file type association. When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access or by administrators using the built-in assoc utility.(Citation: Microsoft Change Default Programs)(Citation: Microsoft File Handlers)(Citation: Microsoft Assoc Oct 2017) Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

System file associations are listed under <code>HKEY_CLASSES_ROOT\.[extension]</code>, for example <code>HKEY_CLASSES_ROOT\.txt</code>. The entries point to a handler for that extension located at <code>HKEY_CLASSES_ROOT\\[handler]</code>. The various commands are then listed as subkeys underneath the shell key at <code>HKEY_CLASSES_ROOT\\[handler]\shell\\[action]\command</code>. For example:

- <code>HKEY_CLASSES_ROOT\txtfile\shell\open\command</code>
- <code>HKEY_CLASSES_ROOT\txtfile\shell\print\command</code>
- <code>HKEY_CLASSES_ROOT\txtfile\shell\printto\command</code>

The values of the keys listed are commands that are executed when the handler opens the file extension. Adversaries can modify these values to continually execute arbitrary commands.(Citation: TrendMicro TROJ-FAKEAV OCT 2012)

Hidden Files and Directories - T1564.001

Adversaries may set files and directories to be hidden to evade detection mechanisms. To prevent normal users from accidentally changing special files on a system, most operating systems have the concept of a 'hidden' file. These files don't show up when a user browses the file system with a GUI or when using normal commands on the command line. Users must explicitly ask to show the hidden files either via a series of Graphical User Interface (GUI) prompts or with command line switches (<code>dir /a</code> for Windows and <code>ls –a</code> for Linux and macOS).

On Linux and Mac, users can mark specific files as hidden simply by putting a "." as the first character in the file or folder name (Citation: Sofacy Komplex Trojan) (Citation: Antiquated Mac Malware). Files and folders that start with a period, '.', are by default hidden from being viewed in the Finder application and standard command-line utilities like "ls". Users must specifically change settings to have these files viewable.

Files on macOS can also be marked with the UF_HIDDEN flag which prevents them from being seen in Finder.app, but still allows them to be seen in Terminal.app (Citation: WireLurker). On Windows, users can mark specific files as hidden by using the attrib.exe binary. Many applications create these hidden files and folders to store information so that it doesn't clutter up the user's workspace. For example, SSH utilities create a .ssh folder that's hidden and contains the user's known hosts and keys.

Additionally, adversaries may name files in a manner that would allow the file to be hidden such as naming a file only a "space" character.

Adversaries can use this to their advantage to hide files and folders anywhere on the system and evading a typical user or system analysis that does not incorporate investigation of hidden files.

Services File Permissions Weakness - T1574.010

Adversaries may execute their own malicious payloads by hijacking the binaries used by services. Adversaries may use flaws in the permissions of Windows services to replace the binary that is executed upon service start. These service processes may automatically execute specific binaries as part of their functionality or to perform other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed

by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

The tag is: *misp-galaxy:mitre-attack-pattern="Services File Permissions Weakness - T1574.010"*

Table 8095. Table References

Links
https://attack.mitre.org/techniques/T1574/010

Exfiltration to Code Repository - T1567.001

Adversaries may exfiltrate data to a code repository rather than over their primary command and control channel. Code repositories are often accessible via an API (ex: https://api.github.com). Access to these APIs are often over HTTPS, which gives the adversary an additional level of protection.

Exfiltration to a code repository can also provide a significant amount of cover to the adversary if it is a popular service already used by hosts within the network.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration to Code Repository - T1567.001"*

Table 8096. Table References

Network Address Translation Traversal - T1599.001

Adversaries may bridge network boundaries by modifying a network device's Network Address Translation (NAT) configuration. Malicious modifications to NAT may enable an adversary to bypass restrictions on traffic routing that otherwise separate trusted and untrusted networks.

Network devices such as routers and firewalls that connect multiple networks together may implement NAT during the process of passing packets between networks. When performing NAT, the network device will rewrite the source and/or destination addresses of the IP address header. Some network designs require NAT for the packets to cross the border device. A typical example of this is environments where internal networks make use of non-Internet routable addresses.(Citation: RFC1918)

When an adversary gains control of a network boundary device, they may modify NAT configurations to send traffic between two separated networks, or to obscure their activities. In network designs that require NAT to function, such modifications enable the adversary to

overcome inherent routing limitations that would normally prevent them from accessing protected systems behind the border device. In network designs that do not require NAT, adversaries may use address translation to further obscure their activities, as changing the addresses of packets that traverse a network boundary device can make monitoring data transmissions more challenging for defenders.

Adversaries may use [Patch System Image](https://attack.mitre.org/techniques/T1601/001) to change the operating system of a network device, implementing their own custom NAT mechanisms to further obscure their activities.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Address Translation Traversal - T1599.001"*

Disable Windows Event Logging - T1562.002

Adversaries may disable Windows event logging to limit data that can be leveraged for detections and audits. Windows event logs record user and system activity such as login attempts, process creation, and much more.(Citation: Windows Log Events) This data is used by security tools and analysts to generate detections.

The EventLog service maintains event logs from various system components and applications.(Citation: EventLog_Core_Technologies) By default, the service automatically starts when a system powers on. An audit policy, maintained by the Local Security Policy (secpol.msc), defines which system events the EventLog service logs. Security audit policy settings can be changed by running secpol.msc, then navigating to <code>Security Settings\Local Policies\Audit Policy</code> for basic audit policy settings or <code>Security Settings\Advanced Audit Policy Configuration</code> for advanced audit policy settings.(Citation: Audit_Policy_Microsoft)(Citation: Advanced_sec_audit_policy_settings) <code>auditpol.exe</code> may also be used to set audit policies.(Citation: auditpol)

Adversaries may target system-wide logging or just that of a particular application. For example, the Windows EventLog service may be disabled using the <code>Set-Service -Name EventLog -Status Stopped</code> or <code>sc config eventlog start=disabled</code> commands (followed by manually stopping the service using <code>Stop-Service -Name EventLog</code>).(Citation: Disable_Win_Event_Logging)(Citation: disable_win_evt_logging) Additionally, the service may be disabled by modifying the “Start” value in <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog</code> then restarting the system for the change to take effect.(Citation: disable_win_evt_logging)

There are several ways to disable the EventLog service via registry key modification. First, without Administrator privileges, adversaries may modify the "Start" value in the key <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\WMI\Autologger\EventLog-Security</code>, then reboot the system to disable the Security EventLog.(Citation:

winser19_file_overwrite_bug_twitter) Second, with Administrator privilege, adversaries may modify the same values in <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\WMI\Autologger\EventLog-System</code> and <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\WMI\Autologger\EventLog-Application</code> to disable the entire EventLog.(Citation: disable_win_evt_logging)

Additionally, adversaries may use <code>auditpol</code> and its sub-commands in a command prompt to disable auditing or clear the audit policy. To enable or disable a specified setting or audit category, adversaries may use the <code>/success</code> or <code>/failure</code> parameters. For example, <code>auditpol /set /category:”Account Logon” /success:disable /failure:disable</code> turns off auditing for the Account Logon category.(Citation: auditpol.exe_STRONTIC)(Citation: T1562.002_redcanaryco) To clear the audit policy, adversaries may run the following lines: <code>auditpol /clear /y</code> or <code>auditpol /remove /allusers</code>.(Citation: T1562.002_redcanaryco)

By disabling Windows event logging, adversaries can operate while leaving less evidence of a compromise behind.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable Windows Event Logging - T1562.002"*

Impair Command History Logging - T1562.003

Adversaries may impair command history logging to hide commands they run on a compromised system. Various command interpreters keep track of the commands users type in their terminal so that users can retrace what they've done.

On Linux and macOS, command history is tracked in a file pointed to by the environment variable <code>HISTFILE</code>. When a user logs off a system, this information is flushed to a file in the user's home directory called <code>~/.bash_history</code>. The <code>HISTCONTROL</code> environment variable keeps track of what should be saved by the <code>history</code> command and eventually into the <code>~/.bash_history</code> file when a user logs out. <code>HISTCONTROL</code> does not exist by default on macOS, but can be set by the user and will be respected. The `HISTFILE` environment variable is also used in some ESXi systems.(Citation: Google Cloud Threat Intelligence ESXi VIBs 2022)

Adversaries may clear the history environment variable (<code>unset HISTFILE</code>) or set the command history size to zero (<code>export HISTFILESIZE=0</code>) to prevent logging of commands. Additionally, <code>HISTCONTROL</code> can be configured to ignore commands that start with a space by simply setting it to "ignorespace". <code>HISTCONTROL</code> can also be set to ignore duplicate commands by setting it to "ignoredups". In some Linux systems, this is set by default to "ignoreboth" which covers both of the previous examples. This means that " ls" will not be saved, but "ls" would be saved by history. Adversaries can abuse this to operate without leaving traces by simply prepending a space to all of their terminal commands.

On Windows systems, the <code>PSReadLine</code> module tracks commands used in all PowerShell sessions and writes them to a file (<code>$env:APPDATA\Microsoft\Windows\PowerShell\PSReadLine\ConsoleHost_history.txt</code> by default). Adversaries may change where these logs are saved using <code>Set-PSReadLineOption -HistorySavePath {File Path}</code>. This will cause <code>ConsoleHost_history.txt</code> to stop receiving logs. Additionally, it is possible to turn off logging to this file using the PowerShell command <code>Set-PSReadlineOption -HistorySaveStyle SaveNothing</code>.(Citation: Microsoft PowerShell Command History)(Citation: Sophos PowerShell command audit)(Citation: Sophos PowerShell Command History Forensics)

Adversaries may also leverage a [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) on network devices to disable historical command logging (e.g. <code>no logging</code>).

The tag is: *misp-galaxy:mitre-attack-pattern="Impair Command History Logging - T1562.003"*

Disable or Modify Tools - T1629.003

Adversaries may disable security tools to avoid potential detection of their tools and activities. This can take the form of disabling security software, modifying SELinux configuration, or other methods to interfere with security tools scanning or reporting information. This is typically done by abusing device administrator permissions or using system exploits to gain root access to the device to modify protected system files.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable or Modify Tools - T1629.003"*

Table 8100. Table References

Bypass User Account Control - T1548.002

Adversaries may bypass UAC mechanisms to elevate process privileges on system. Windows User Account Control (UAC) allows a program to elevate its privileges (tracked as integrity levels ranging from low to high) to perform a task under administrator-level permissions, possibly by prompting the user for confirmation. The impact to the user ranges from denying the operation under high enforcement to allowing the user to perform the action if they are in the local administrators group and click through the prompt or allowing them to enter an administrator password to complete the action.(Citation: TechNet How UAC Works)

If the UAC protection level of a computer is set to anything but the highest level, certain Windows programs can elevate privileges or execute some elevated [Component Object Model](https://attack.mitre.org/techniques/T1559/001) objects without prompting the user through the UAC notification box.(Citation: TechNet Inside UAC)(Citation: MSDN COM Elevation) An example of this is use of [Rundll32](https://attack.mitre.org/techniques/T1218/011) to load a specifically crafted DLL which loads an auto-elevated [Component Object Model](https://attack.mitre.org/techniques/T1559/001) object and performs a file operation in a protected directory which would typically require elevated access. Malicious software may also be injected into a trusted process to gain elevated privileges without prompting a user.(Citation: Davidson Windows)

Many methods have been discovered to bypass UAC. The Github readme page for UACME contains an extensive list of methods(Citation: Github UACMe) that have been discovered and implemented, but may not be a comprehensive list of bypasses. Additional bypass methods are regularly discovered and some used in the wild, such as:

- <code>eventvwr.exe</code> can auto-elevate and execute a specified binary or script.(Citation: enigma0x3 Fileless UAC Bypass)(Citation: Fortinet Fareit)

Another bypass is possible through some lateral movement techniques if credentials for an account with administrator privileges are known, since UAC is a single system security mechanism, and the privilege or integrity of a process running on one system will be unknown on remote systems and default to high integrity.(Citation: SANS UAC Bypass)

The tag is: *misp-galaxy:mitre-attack-pattern="Bypass User Account Control - T1548.002"*

User Activity Based Checks - T1497.002

Adversaries may employ various user activity checks to detect and avoid virtualization and analysis environments. This may include changing behaviors based on the results of checks for the presence of artifacts indicative of a virtual machine environment (VME) or sandbox. If the adversary detects a VME, they may alter their malware to disengage from the victim or conceal the core functions of the implant. They may also search for VME artifacts before dropping secondary or additional payloads. Adversaries may use the information learned from [Virtualization/Sandbox Evasion](https://attack.mitre.org/techniques/T1497) during automated discovery to shape follow-on behaviors.(Citation: Deloitte Environment Awareness)

Adversaries may search for user activity on the host based on variables such as the speed/frequency of mouse movements and clicks (Citation: Sans Virtual Jan 2016) , browser history, cache, bookmarks, or number of files in common directories such as home or the desktop. Other methods may rely on specific user interaction with the system before the malicious code is activated, such as waiting for a document to close before activating a macro (Citation: Unit 42 Sofacy Nov 2018) or waiting for a user to double click on an embedded image to activate.(Citation: FireEye FIN7 April 2017)

Cloud Instance Metadata API - T1552.005

Adversaries may attempt to access the Cloud Instance Metadata API to collect credentials and other sensitive data.

Most cloud service providers support a Cloud Instance Metadata API which is a service provided to running virtual instances that allows applications to access information about the running virtual instance. Available information generally includes name, security group, and additional metadata

including sensitive data such as credentials and UserData scripts that may contain additional secrets. The Instance Metadata API is provided as a convenience to assist in managing applications and is accessible by anyone who can access the instance.(Citation: AWS Instance Metadata API) A cloud metadata API has been used in at least one high profile compromise.(Citation: Krebs Capital One August 2019)

If adversaries have a presence on the running virtual instance, they may query the Instance Metadata API directly to identify credentials that grant access to additional resources. Additionally, adversaries may exploit a Server-Side Request Forgery (SSRF) vulnerability in a public facing web proxy that allows them to gain access to the sensitive information via a request to the Instance Metadata API.(Citation: RedLock Instance Metadata API 2018)

The de facto standard across cloud service providers is to host the Instance Metadata API at <code>http[:]//169.254.169.254</code>.

Exfiltration to Cloud Storage - T1567.002

Adversaries may exfiltrate data to a cloud storage service rather than over their primary command and control channel. Cloud storage services allow for the storage, edit, and retrieval of data from a remote cloud storage server over the Internet.

Examples of cloud storage services include Dropbox and Google Docs. Exfiltration to these cloud storage services can provide a significant amount of cover to the adversary if hosts within the network are already communicating with the service.

Compromise Software Supply Chain - T1474.003

Adversaries may manipulate application software prior to receipt by a final consumer for the purpose of data or system compromise. Supply chain compromise of software can take place in a number of ways, including manipulation of the application source code, manipulation of the update/distribution mechanism for that software, or replacing compiled releases with a modified

version.

Sudo and Sudo Caching - T1548.003

Adversaries may perform sudo caching and/or use the sudoers file to elevate privileges. Adversaries may do this to execute commands as other users or spawn processes with higher privileges.

Within Linux and MacOS systems, sudo (sometimes referred to as "superuser do") allows users to perform commands from terminals with elevated privileges and to control who can perform these commands on the system. The <code>sudo</code> command "allows a system administrator to delegate authority to give certain users (or groups of users) the ability to run some (or all) commands as root or another user while providing an audit trail of the commands and their arguments."(Citation: sudo man page 2018) Since sudo was made for the system administrator, it has some useful configuration features such as a <code>timestamp_timeout</code>, which is the amount of time in minutes between instances of <code>sudo</code> before it will re-prompt for a password. This is because <code>sudo</code> has the ability to cache credentials for a period of time. Sudo creates (or touches) a file at <code>/var/db/sudo</code> with a timestamp of when sudo was last run to determine this timeout. Additionally, there is a <code>tty_tickets</code> variable that treats each new tty (terminal session) in isolation. This means that, for example, the sudo timeout of one tty will not affect another tty (you will have to type the password again).

The sudoers file, <code>/etc/sudoers</code>, describes which users can run which commands and from which terminals. This also describes which commands users can run as other users or groups. This provides the principle of least privilege such that users are running in their lowest possible permissions for most of the time and only elevate to other users or permissions as needed, typically by prompting for a password. However, the sudoers file can also specify when to not prompt users for passwords with a line like <code>user1 ALL=(ALL) NOPASSWD: ALL</code>.(Citation: OSX.Dok Malware) Elevated privileges are required to edit this file though.

Adversaries can also abuse poor configurations of these mechanisms to escalate privileges without needing the user’s password. For example, <code>/var/db/sudo</code>'s timestamp can be monitored to see if it falls within the <code>timestamp_timeout</code> range. If it does, then malware can execute sudo commands without needing to supply the user’s password. Additional, if <code>tty_tickets</code> is disabled, adversaries can do this from any tty for that user.

In the wild, malware has disabled <code>tty_tickets</code> to potentially make scripting easier by issuing <code>echo \'Defaults !tty_tickets\' >> /etc/sudoers</code>.(Citation: cybereason osx proton) In order for this change to be reflected, the malware also issued <code>killall Terminal</code>. As of macOS Sierra, the sudoers file has <code>tty_tickets</code> enabled by default.

Credentials from Web Browsers - T1555.003

Adversaries may acquire credentials from web browsers by reading files specific to the target browser.(Citation: Talos Olympic Destroyer 2018) Web browsers commonly save credentials such as website usernames and passwords so that they do not need to be entered manually in the future. Web browsers typically store the credentials in an encrypted format within a credential store; however, methods exist to extract plaintext credentials from web browsers.

For example, on Windows systems, encrypted credentials may be obtained from Google Chrome by reading a database file, <code>AppData\Local\Google\Chrome\User Data\Default\Login Data</code> and executing a SQL query: <code>SELECT action_url, username_value, password_value FROM logins;</code>. The plaintext password can then be obtained by passing the encrypted credentials to the Windows API function <code>CryptUnprotectData</code>, which uses the victim's cached logon credentials as the decryption key.(Citation: Microsoft CryptUnprotectData April 2018)

Adversaries have executed similar procedures for common web browsers such as FireFox, Safari, Edge, etc.(Citation: Proofpoint Vega Credential Stealer May 2018)(Citation: FireEye HawkEye Malware July 2017) Windows stores Internet Explorer and Microsoft Edge credentials in Credential Lockers managed by the [Windows Credential Manager](https://attack.mitre.org/techniques/T1555/004).

Adversaries may also acquire credentials by searching web browser process memory for patterns that commonly match credentials.(Citation: GitHub Mimikittenz July 2016)

After acquiring credentials from web browsers, adversaries may attempt to recycle the credentials across different systems and/or accounts in order to expand access. This can result in significantly furthering an adversary's objective in cases where credentials gained from web browsers overlap with privileged accounts (e.g. domain administrator).

Code Signing Policy Modification - T1553.006

Adversaries may modify code signing policies to enable execution of unsigned or self-signed code. Code signing provides a level of authenticity on a program from a developer and a guarantee that the program has not been tampered with. Security controls can include enforcement mechanisms to ensure that only valid, signed code can be run on an operating system.

Some of these security controls may be enabled by default, such as Driver Signature Enforcement (DSE) on Windows or System Integrity Protection (SIP) on macOS.(Citation: Microsoft DSE June 2017)(Citation: Apple Disable SIP) Other such controls may be disabled by default but are configurable through application controls, such as only allowing signed Dynamic-Link Libraries (DLLs) to execute on a system. Since it can be useful for developers to modify default signature enforcement policies during the development and testing of applications, disabling of these features may be possible with elevated permissions.(Citation: Microsoft Unsigned Driver Apr 2017)(Citation: Apple Disable SIP)

Adversaries may modify code signing policies in a number of ways, including through use of command-line or GUI utilities, [Modify Registry](https://attack.mitre.org/techniques/T1112), rebooting the computer in a debug/recovery mode, or by altering the value of variables in kernel memory.(Citation: Microsoft TESTSIGNING Feb 2021)(Citation: Apple Disable SIP)(Citation: FireEye HIKIT Rootkit Part 2)(Citation: GitHub Turla Driver Loader) Examples of commands that can modify the code signing policy of a system include <code>bcdedit.exe -set TESTSIGNING ON</code> on Windows and <code>csrutil disable</code> on macOS.(Citation: Microsoft TESTSIGNING Feb 2021)(Citation: Apple Disable SIP) Depending on the implementation, successful modification of a signing policy may require reboot of the compromised system. Additionally, some implementations can introduce visible artifacts for the user (ex: a watermark in the corner of the screen stating the system is in Test Mode). Adversaries may attempt to remove such artifacts.(Citation: F-Secure BlackEnergy 2014)

To gain access to kernel memory to modify variables related to signature checks, such as modifying <code>g_CiOptions</code> to disable Driver Signature Enforcement, adversaries may conduct [Exploitation for Privilege Escalation](https://attack.mitre.org/techniques/T1068) using a signed, but vulnerable driver.(Citation: Unit42 AcidBox June 2020)(Citation: GitHub Turla Driver Loader)

Unix Shell Configuration Modification - T1546.004

Adversaries may establish persistence through executing malicious commands triggered by a user's shell. User [Unix Shell](https://attack.mitre.org/techniques/T1059/004)s execute several configuration scripts at different points throughout the session based on events. For example, when a user opens a command-line interface or remotely logs in (such as via SSH) a login shell is initiated. The login shell executes scripts from the system (<code>/etc</code>) and the user's home directory (<code>~/</code>) to configure the environment. All login shells on a system use /etc/profile when initiated. These configuration scripts run at the permission level of their directory and are often used to set environment variables, create aliases, and customize the user's environment. When the shell exits or terminates, additional shell scripts are executed to ensure the shell exits appropriately.

Adversaries may attempt to establish persistence by inserting commands into scripts automatically executed by shells. Using bash as an example, the default shell for most GNU/Linux systems, adversaries may add commands that launch malicious binaries into the <code>/etc/profile</code> and <code>/etc/profile.d</code> files.(Citation: intezer-kaiji-malware)(Citation: bencane blog bashrc) These files typically require root permissions to modify and are executed each time any shell on a system launches. For user level permissions, adversaries can insert malicious commands into <code>~/.bash_profile</code>, <code>~/.bash_login</code>, or <code>~/.profile</code> which are sourced when a user opens a command-line interface or connects remotely.(Citation: anomali-rocke-tactics)(Citation: Linux manual bash invocation) Since the system only executes the first existing file in the listed order, adversaries have used <code>~/.bash_profile</code> to ensure execution. Adversaries have also leveraged the <code>~/.bashrc</code> file which is additionally executed if the connection is established remotely or an additional interactive shell is opened, such as a new tab in the command-line interface.(Citation: Tsunami)(Citation: anomali-rocke-

tactics)(Citation: anomali-linux-rabbit)(Citation: Magento) Some malware targets the termination of a program to trigger execution, adversaries can use the <code>~/.bash_logout</code> file to execute malicious commands at the end of a session.

For macOS, the functionality of this technique is similar but may leverage zsh, the default shell for macOS 10.15+. When the Terminal.app is opened, the application launches a zsh login shell and a zsh interactive shell. The login shell configures the system environment using <code>/etc/profile</code>, <code>/etc/zshenv</code>, <code>/etc/zprofile</code>, and <code>/etc/zlogin</code>.(Citation: ScriptingOSX zsh)(Citation: PersistentJXA_leopitt)(Citation: code_persistence_zsh)(Citation: macOS MS office sandbox escape) The login shell then configures the user environment with <code>~/.zprofile</code> and <code>~/.zlogin</code>. The interactive shell uses the <code>~/.zshrc</code> to configure the user environment. Upon exiting, <code>/etc/zlogout</code> and <code>~/.zlogout</code> are executed. For legacy programs, macOS executes <code>/etc/bashrc</code> on startup.

Elevated Execution with Prompt - T1548.004

Adversaries may leverage the <code>AuthorizationExecuteWithPrivileges</code> API to escalate privileges by prompting the user for credentials.(Citation: AppleDocs AuthorizationExecuteWithPrivileges) The purpose of this API is to give application developers an easy way to perform operations with root privileges, such as for application installation or updating. This API does not validate that the program requesting root privileges comes from a

reputable source or has been maliciously modified.

Although this API is deprecated, it still fully functions in the latest releases of macOS. When calling this API, the user will be prompted to enter their credentials but no checks on the origin or integrity of the program are made. The program calling the API may also load world writable files which can be modified to perform malicious behavior with elevated privileges.

Adversaries may abuse <code>AuthorizationExecuteWithPrivileges</code> to obtain root privileges in order to install malicious software on victims and install persistence mechanisms.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019)(Citation: OSX Coldroot RAT) This technique may be combined with [Masquerading](https://attack.mitre.org/techniques/T1036) to trick the user into granting escalated privileges to malicious code.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019) This technique has also been shown to work by modifying legitimate programs present on the machine that make use of this API.(Citation: Death by 1000 installers; it's all broken!)

Application or System Exploitation - T1499.004

Adversaries may exploit software vulnerabilities that can cause an application or system to crash and deny availability to users. (Citation: Sucuri BIND9 August 2015) Some systems may automatically restart critical applications and services when crashes occur, but they can likely be re-exploited to cause a persistent denial of service (DoS) condition.

Adversaries may exploit known or zero-day vulnerabilities to crash applications and/or systems, which may also lead to dependent applications and/or systems to be in a DoS condition. Crashed or restarted applications or systems may also have other effects such as [Data Destruction](https://attack.mitre.org/techniques/T1485), [Firmware Corruption](https://attack.mitre.org/techniques/T1495), [Service Stop](https://attack.mitre.org/techniques/T1489) etc. which may further cause a DoS condition and deny availability to critical information, applications and/or systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Application or System Exploitation - T1499.004"*

Table 8112. Table References

Temporary Elevated Cloud Access - T1548.005

Adversaries may abuse permission configurations that allow them to gain temporarily elevated access to cloud resources. Many cloud environments allow administrators to grant user or service accounts permission to request just-in-time access to roles, impersonate other accounts, pass roles onto resources and services, or otherwise gain short-term access to a set of privileges that may be distinct from their own.

Just-in-time access is a mechanism for granting additional roles to cloud accounts in a granular, temporary manner. This allows accounts to operate with only the permissions they need on a daily basis, and to request additional permissions as necessary. Sometimes just-in-time access requests are configured to require manual approval, while other times the desired permissions are automatically granted.(Citation: Azure Just in Time Access 2023)

Account impersonation allows user or service accounts to temporarily act with the permissions of another account. For example, in GCP users with the `iam.serviceAccountTokenCreator` role can create temporary access tokens or sign arbitrary payloads with the permissions of a service account, while service accounts with domain-wide delegation permission are permitted to impersonate Google Workspace accounts.(Citation: Google Cloud Service Account Authentication Roles)(Citation: Hunters Domain Wide Delegation Google Workspace 2023)(Citation: Google Cloud Just in Time Access 2023)(Citation: Palo Alto Unit 42 Google Workspace Domain Wide Delegation 2023) In Exchange Online, the `ApplicationImpersonation` role allows a service account to use the permissions associated with specified user accounts.(Citation: Microsoft Impersonation and EWS in Exchange)

Many cloud environments also include mechanisms for users to pass roles to resources that allow them to perform tasks and authenticate to other services. While the user that creates the resource does not directly assume the role they pass to it, they may still be able to take advantage of the role's access — for example, by configuring the resource to perform certain actions with the permissions it has been granted. In AWS, users with the `PassRole` permission can allow a service they create to assume a given role, while in GCP, users with the `iam.serviceAccountUser` role can attach a service account to a resource.(Citation: AWS PassRole)(Citation: Google Cloud Service Account Authentication Roles)

While users require specific role assignments in order to use any of these features, cloud administrators may misconfigure permissions. This could result in escalation paths that allow adversaries to gain access to resources beyond what was originally intended.(Citation: Rhino Google Cloud Privilege Escalation)(Citation: Rhino Security Labs AWS Privilege Escalation)

Note: this technique is distinct from [Additional Cloud Roles](https://attack.mitre.org/techniques/T1098/003), which involves assigning permanent roles to accounts rather than abusing existing permissions structures to gain temporarily elevated access to resources. However, adversaries that compromise a sufficiently privileged account may grant another account they control [Additional Cloud Roles](https://attack.mitre.org/techniques/T1098/003) that would allow them to also abuse these features. This may also allow for greater stealth than would be had by directly using the highly privileged account, especially when logs do not clarify when role impersonation is taking

place.(Citation: CrowdStrike StellarParticle January 2022)

The tag is: *misp-galaxy:mitre-attack-pattern="Temporary Elevated Cloud Access - T1548.005"*

Kernel Modules and Extensions - T1547.006

Adversaries may modify the kernel to automatically execute programs on system boot. Loadable Kernel Modules (LKMs) are pieces of code that can be loaded and unloaded into the kernel upon demand. They extend the functionality of the kernel without the need to reboot the system. For example, one type of module is the device driver, which allows the kernel to access hardware connected to the system.(Citation: Linux Kernel Programming)

When used maliciously, LKMs can be a type of kernel-mode [Rootkit](https://attack.mitre.org/techniques/T1014) that run with the highest operating system privilege (Ring 0).(Citation: Linux Kernel Module Programming Guide) Common features of LKM based rootkits include: hiding itself, selective hiding of files, processes and network activity, as well as log tampering, providing authenticated backdoors, and enabling root access to non-privileged users.(Citation: iDefense Rootkit Overview)

Kernel extensions, also called kext, are used in macOS to load functionality onto a system similar to LKMs for Linux. Since the kernel is responsible for enforcing security and the kernel extensions run as apart of the kernel, kexts are not governed by macOS security policies. Kexts are loaded and unloaded through <code>kextload</code> and <code>kextunload</code> commands. Kexts need to be signed with a developer ID that is granted privileges by Apple allowing it to sign Kernel extensions. Developers without these privileges may still sign kexts but they will not load unless SIP is disabled. If SIP is enabled, the kext signature is verified before being added to the

AuxKC.(Citation: System and kernel extensions in macOS)

Since macOS Catalina 10.15, kernel extensions have been deprecated in favor of System Extensions. However, kexts are still allowed as "Legacy System Extensions" since there is no System Extension for Kernel Programming Interfaces.(Citation: Apple Kernel Extension Deprecation)

Adversaries can use LKMs and kexts to conduct [Persistence](https://attack.mitre.org/tactics/TA0003) and/or [Privilege Escalation](https://attack.mitre.org/tactics/TA0004) on a system. Examples have been found in the wild, and there are some relevant open source projects as well.(Citation: Volatility Phalanx2)(Citation: CrowdStrike Linux Rootkit)(Citation: GitHub Reptile)(Citation: GitHub Diamorphine)(Citation: RSAC 2015 San Francisco Patrick Wardle)(Citation: Synack Secure Kernel Extension Broken)(Citation: Securelist Ventir)(Citation: Trend Micro Skidmap)

Cloud Secrets Management Stores - T1555.006

Adversaries may acquire credentials from cloud-native secret management solutions such as AWS Secrets Manager, GCP Secret Manager, Azure Key Vault, and Terraform Vault.

Secrets managers support the secure centralized management of passwords, API keys, and other credential material. Where secrets managers are in use, cloud services can dynamically acquire credentials via API requests rather than accessing secrets insecurely stored in plain text files or environment variables.

If an adversary is able to gain sufficient privileges in a cloud environment – for example, by obtaining the credentials of high-privileged [Cloud Accounts](https://attack.mitre.org/techniques/T1078/004) or compromising a service that has permission to retrieve secrets – they may be able to request secrets from the secrets manager. This can be accomplished via commands such as `get-secret-value` in AWS, `gcloud secrets describe` in GCP, and `az key vault secret show` in Azure.(Citation: Permiso Scattered Spider 2023)(Citation: Sysdig ScarletEel 2.0 2023)(Citation: AWS Secrets Manager)(Citation: Google Cloud Secrets)(Citation: Microsoft Azure Key Vault)

Note: this technique is distinct from [Cloud Instance Metadata API](https://attack.mitre.org/techniques/T1552/005) in that the credentials are being directly requested from the cloud secrets manager, rather than through the medium of the instance metadata API.

Modify Cloud Compute Configurations - T1578.005

Adversaries may modify settings that directly affect the size, locations, and resources available to cloud compute infrastructure in order to evade defenses. These settings may include service quotas, subscription associations, tenant-wide policies, or other configurations that impact available compute. Such modifications may allow adversaries to abuse the victim's compute resources to achieve their goals, potentially without affecting the execution of running instances and/or revealing their activities to the victim.

For example, cloud providers often limit customer usage of compute resources via quotas. Customers may request adjustments to these quotas to support increased computing needs, though these adjustments may require approval from the cloud provider. Adversaries who compromise a cloud environment may similarly request quota adjustments in order to support their activities,

such as enabling additional [Resource Hijacking](https://attack.mitre.org/techniques/T1496) without raising suspicion by using up a victim's entire quota.(Citation: Microsoft Cryptojacking 2023) Adversaries may also increase allowed resource usage by modifying any tenant-wide policies that limit the sizes of deployed virtual machines.(Citation: Microsoft Azure Policy)

Adversaries may also modify settings that affect where cloud resources can be deployed, such as enabling [Unused/Unsupported Cloud Regions](https://attack.mitre.org/techniques/T1535).

Services Registry Permissions Weakness - T1574.011

Adversaries may execute their own malicious payloads by hijacking the Registry entries used by services. Flaws in the permissions for Registry keys related to services can allow adversaries to redirect the originally specified executable to one they control, launching their own code when a service starts. Windows stores local service configuration information in the Registry under <code>HKLM\SYSTEM\CurrentControlSet\Services</code>. The information stored under a service's Registry keys can be manipulated to modify a service's execution parameters through tools such as the service controller, sc.exe, [PowerShell](https://attack.mitre.org/techniques/T1059/001), or [Reg](https://attack.mitre.org/software/S0075). Access to Registry keys is controlled through access control lists and user permissions. (Citation: Registry Key Security)(Citation: malware_hides_service)

If the permissions for users and groups are not properly set and allow access to the Registry keys for a service, adversaries may change the service's binPath/ImagePath to point to a different executable under their control. When the service starts or is restarted, the adversary-controlled program will execute, allowing the adversary to establish persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService).

Adversaries may also alter other Registry keys in the service's Registry tree. For example, the <code>FailureCommand</code> key may be changed so that the service is executed in an elevated context anytime the service fails or is intentionally corrupted.(Citation: Kansa Service related collectors)(Citation: Tweet Registry Perms Weakness)

The <code>Performance</code> key contains the name of a driver service's performance DLL and the names of several exported functions in the DLL.(Citation: microsoft_services_registry_tree) If the <code>Performance</code> key is not already present and if an adversary-controlled user has the <code>Create Subkey</code> permission, adversaries may create the <code>Performance</code> key in the service's Registry tree to point to a malicious DLL.(Citation:

insecure_reg_perms)

Adversaries may also add the <code>Parameters</code> key, which can reference malicious drivers file paths. This technique has been identified to be a method of abuse by configuring DLL file paths within the <code>Parameters</code> key of a given services registry configuration. By placing and configuring the <code>Parameters</code> key to reference a malicious DLL, adversaries can ensure that their code is loaded persistently whenever the associated service or library is invoked.

For example, the registry path(Citation: MDSec) <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\WinSock2\Parameters</code>(Citation: hexacorn)(Citation: gendigital) contains the <code>AutodiaDLL</code> value, which specifies the DLL to be loaded for autodial funcitionality. An adversary could set the <code>AutodiaDLL</code> to point to a hijacked or malicious DLL:

<code>"AutodialDLL"="c:\temp\foo.dll"</code>

This ensures persistence, as it causes the DLL (in this case, foo.dll) to be loaded each time the Winsock 2 library is invoked.

Component Object Model Hijacking - T1546.015

Adversaries may establish persistence by executing malicious content triggered by hijacked references to Component Object Model (COM) objects. COM is a system within Windows to enable interaction between software components through the operating system.(Citation: Microsoft Component Object Model) References to various COM objects are stored in the Registry.

Adversaries may use the COM system to insert malicious code that can be executed in place of legitimate software through hijacking the COM references and relationships as a means for persistence. Hijacking a COM object requires a change in the Registry to replace a reference to a legitimate system component which may cause that component to not work when executed. When that system component is executed through normal system operation the adversary's code will be executed instead.(Citation: GDATA COM Hijacking) An adversary is likely to hijack objects that are used frequently enough to maintain a consistent level of persistence, but are unlikely to break noticeable functionality within the system as to avoid system instability that could lead to detection.

One variation of COM hijacking involves abusing Type Libraries (TypeLibs), which provide metadata about COM objects, such as their interfaces and methods. Adversaries may modify Registry keys associated with TypeLibs to redirect legitimate COM object functionality to malicious scripts or payloads. Unlike traditional COM hijacking, which commonly uses local DLLs, this variation may leverage the "script:" moniker to execute remote scripts hosted on external servers.(Citation: RELIAQUEST) This approach enables stealthy execution of code while maintaining persistence, as the remote payload would be automatically downloaded whenever the hijacked COM object is accessed.

Deobfuscate/Decode Files or Information - T1140

Adversaries may use [Obfuscated Files or Information](https://attack.mitre.org/techniques/T1027) to hide artifacts of an intrusion from analysis. They may require separate mechanisms to decode or deobfuscate that information depending on how they intend to use it. Methods for doing that include built-in functionality of malware or by using utilities present on the system.

One such example is the use of [certutil](https://attack.mitre.org/software/S0160) to decode a remote access tool portable executable file that has been hidden inside a certificate file.(Citation: Malwarebytes Targeted Attack against Saudi Arabia) Another example is using the Windows <code>copy /b</code> or <code>type</code> command to reassemble binary fragments into a malicious payload.(Citation: Carbon Black Obfuscation Sept 2016)(Citation: Sentinel One Tainted Love 2023)

Sometimes a user's action may be required to open it for deobfuscation or decryption as part of [User Execution](https://attack.mitre.org/techniques/T1204). The user may also be required to input a password to open a password protected compressed/encrypted file that was provided by the

adversary.(Citation: Volexity PowerDuke November 2016)

https://attack.mitre.org/techniques/T1041

Exploitation of Remote Services - T1210

Adversaries may exploit remote services to gain unauthorized access to internal systems once inside of a network. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. A common goal for post-compromise exploitation of remote services is for lateral movement to enable access to a remote system.

An adversary may need to determine if the remote system is in a vulnerable state, which may be done through [Network Service Discovery](https://attack.mitre.org/techniques/T1046) or other Discovery methods looking for common, vulnerable software that may be deployed in the network, the lack of certain patches that may indicate vulnerabilities, or security software that may be used to detect or contain remote exploitation. Servers are likely a high value target for lateral movement exploitation, but endpoint systems may also be at risk if they provide an advantage or access to additional resources.

There are several well-known vulnerabilities that exist in common services such as SMB(Citation: CIS Multiple SMB Vulnerabilities) and RDP(Citation: NVD CVE-2017-0176) as well as applications that may be used within internal networks such as MySQL(Citation: NVD CVE-2016-6662) and web server services.(Citation: NVD CVE-2014-7169)(Citation: Ars Technica VMWare Code Execution

Vulnerability 2021) Additionally, there have been a number of vulnerabilities in VMware vCenter installations, which may enable threat actors to move laterally from the compromised vCenter server to virtual machines or even to ESXi hypervisors.(Citation: Broadcom VMSA-2024-0019)

Depending on the permissions level of the vulnerable remote service an adversary may achieve [Exploitation for Privilege Escalation](https://attack.mitre.org/techniques/T1068) as a result of lateral movement exploitation as well.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation of Remote Services - T1210"*

System Network Configuration Discovery - T1016

Adversaries may look for details about the network configuration and settings, such as IP and/or MAC addresses, of systems they access or through information discovery of remote systems. Several operating system administration utilities exist that can be used to gather this information. Examples include [Arp](https://attack.mitre.org/software/S0099), [ipconfig](ifconfig (https://attack.mitre.org/software/S0101), [nbtstat](https://attack.mitre.org/software/S0102), and [route](https://attack.mitre.org/software/S0103).

Adversaries may also leverage a [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) on network devices to gather information about configurations and settings, such as IP addresses of configured interfaces and static/dynamic routes (e.g. <code>show ip route</code>, <code>show ip interface</code>).(Citation: US-CERT-TA18-106A)(Citation: Mandiant APT41 Global Intrusion) On ESXi, adversaries may leverage esxcli to gather network configuration information. For example, the command `esxcli network nic list` will retrieve the MAC address, while `esxcli network ip interface ipv4 get` will retrieve the local IPv4 address.(Citation: Trellix Rnasomhouse 2024)

Adversaries may use the information from [System Network Configuration Discovery](https://attack.mitre.org/techniques/T1016) during automated discovery to shape follow-on behaviors, including determining certain access within the target network and what actions to do next.

Replication Through Removable Media - T1091

Adversaries may move onto systems, possibly those on disconnected or air-gapped networks, by copying malware to removable media and taking advantage of Autorun features when the media is inserted into a system and executes. In the case of Lateral Movement, this may occur through modification of executable files stored on removable media or by copying malware and renaming it to look like a legitimate file to trick users into executing it on a separate system. In the case of Initial Access, this may occur through manual manipulation of the media, modification of systems used to initially format the media, or modification to the media's firmware itself.

Mobile devices may also be used to infect PCs with malware if connected via USB.(Citation: Exploiting Smartphone USB) This infection may be achieved using devices (Android, iOS, etc.) and, in some instances, USB charging cables.(Citation: Windows Malware Infecting Android)(Citation: iPhone Charging Cable Hack) For example, when a smartphone is connected to a system, it may appear to be mounted similar to a USB-connected disk drive. If malware that is compatible with the connected system is on the mobile device, the malware could infect the machine (especially if Autorun features are enabled).

Exploitation for Client Execution - T1203

Adversaries may exploit software vulnerabilities in client applications to execute code. Vulnerabilities can exist in software due to unsecure coding practices that can lead to unanticipated behavior. Adversaries can take advantage of certain vulnerabilities through targeted exploitation for the purpose of arbitrary code execution. Oftentimes the most valuable exploits to an offensive

toolkit are those that can be used to obtain code execution on a remote system because they can be used to gain access to that system. Users will expect to see files related to the applications they commonly used to do work, so they are a useful target for exploit research and development because of their high utility.

Several types exist:

Browser-based Exploitation

Web browsers are a common target through [Drive-by Compromise](https://attack.mitre.org/techniques/T1189) and [Spearphishing Link](https://attack.mitre.org/techniques/T1566/002). Endpoint systems may be compromised through normal web browsing or from certain users being targeted by links in spearphishing emails to adversary controlled sites used to exploit the web browser. These often do not require an action by the user for the exploit to be executed.

Office Applications

Common office and productivity applications such as Microsoft Office are also targeted through [Phishing](https://attack.mitre.org/techniques/T1566). Malicious files will be transmitted directly as attachments or through links to download them. These require the user to open the document or file for the exploit to run.

Common Third-party Applications

Other applications that are commonly seen or are part of the software deployed in a target network may also be used for exploitation. Applications such as Adobe Reader and Flash, which are common in enterprise environments, have been routinely targeted by adversaries attempting to gain access to systems. Depending on the software and nature of the vulnerability, some may be exploited in the browser or require the user to open a file. For instance, some Flash exploits have been delivered as objects within Microsoft Office documents.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation for Client Execution - T1203"*

https://attack.mitre.org/techniques/T1203

Change Default File Association - T1042

When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access (Citation: Microsoft Change Default Programs) (Citation: Microsoft File Handlers) or by administrators using the built-in assoc utility. (Citation: Microsoft Assoc Oct 2017) Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

System file associations are listed under <code>HKEY_CLASSES_ROOT\.[extension]</code>, for example <code>HKEY_CLASSES_ROOT\.txt</code>. The entries point to a handler for that extension located at <code>HKEY_CLASSES_ROOT\[handler]</code>. The various commands are then listed as subkeys underneath the shell key at <code>HKEY_CLASSES_ROOT\[handler]\shell\[action]\command</code>. For example: * <code>HKEY_CLASSES_ROOT\txtfile\shell\open\command</code> * <code>HKEY_CLASSES_ROOT\txtfile\shell\print\command</code> * <code>HKEY_CLASSES_ROOT\txtfile\shell\printto\command</code>

The values of the keys listed are commands that are executed when the handler opens the file extension. Adversaries can modify these values to continually execute arbitrary commands. (Citation: TrendMicro TROJ-FAKEAV OCT 2012)

File and Directory Discovery - T1420

Adversaries may enumerate files and directories or search in specific device locations for desired information within a filesystem. Adversaries may use the information from [File and Directory Discovery](https://attack.mitre.org/techniques/T1420) during automated discovery to shape follow-on behaviors, including deciding if the adversary should fully infect the target and/or attempt specific actions.

On Android, Linux file permissions and SELinux policies typically stringently restrict what can be accessed by apps without taking advantage of a privilege escalation exploit. The contents of the external storage directory are generally visible, which could present concerns if sensitive data is inappropriately stored there. iOS's security architecture generally restricts the ability to perform any type of [File and Directory Discovery](https://attack.mitre.org/techniques/T1420) without use of escalated privileges.

Obfuscated Files or Information - T1027

Adversaries may attempt to make an executable or file difficult to discover or analyze by encrypting, encoding, or otherwise obfuscating its contents on the system or in transit. This is common behavior that can be used across different platforms and the network to evade defenses.

Payloads may be compressed, archived, or encrypted in order to avoid detection. These payloads may be used during Initial Access or later to mitigate detection. Sometimes a user's action may be required to open and [Deobfuscate/Decode Files or Information](https://attack.mitre.org/techniques/T1140) for [User Execution](https://attack.mitre.org/techniques/T1204). The user may also be required to input a password to open a password protected compressed/encrypted file that was provided by the adversary. (Citation: Volexity PowerDuke November 2016) Adversaries may also use compressed or archived scripts, such as JavaScript.

Portions of files can also be encoded to hide the plain-text strings that would otherwise help defenders with discovery. (Citation: Linux/Cdorked.A We Live Security Analysis) Payloads may also be split into separate, seemingly benign files that only reveal malicious functionality when reassembled. (Citation: Carbon Black Obfuscation Sept 2016)

Adversaries may also abuse [Command Obfuscation](https://attack.mitre.org/techniques/T1027/010) to obscure commands executed from payloads or directly via [Command and Scripting Interpreter](https://attack.mitre.org/techniques/T1059). Environment variables, aliases, characters, and other platform/language specific semantics can be used to evade signature based detections and application control mechanisms. (Citation: FireEye Obfuscation June 2017) (Citation: FireEye Revoke-Obfuscation July 2017)(Citation: PaloAlto EncodedCommand March 2017)

Communication Through Removable Media - T1092

Adversaries can perform command and control between compromised hosts on potentially disconnected networks using removable media to transfer commands from system to system.(Citation: ESET Sednit USBStealer 2014) Both systems would need to be compromised, with the likelihood that an Internet-connected system was compromised first and the second through lateral movement by [Replication Through Removable Media](https://attack.mitre.org/techniques/T1091). Commands and files would be relayed from the disconnected system to the Internet-connected system to which the adversary has direct access.

Modify Cached Executable Code - T1403

ART (the Android Runtime) compiles optimized code on the device itself to improve performance. An adversary may be able to use escalated privileges to modify the cached code in order to hide malicious behavior. Since the code is compiled on the device, it may not receive the same level of integrity checks that are provided to code running in the system partition.(Citation: Sabanal-ART)

Credentials from Web Browsers - T1503

Adversaries may acquire credentials from web browsers by reading files specific to the target browser. (Citation: Talos Olympic Destroyer 2018)

Web browsers commonly save credentials such as website usernames and passwords so that they do not need to be entered manually in the future. Web browsers typically store the credentials in an encrypted format within a credential store; however, methods exist to extract plaintext credentials from web browsers.

For example, on Windows systems, encrypted credentials may be obtained from Google Chrome by reading a database file, <code>AppData\Local\Google\Chrome\User Data\Default\Login Data</code> and executing a SQL query: <code>SELECT action_url, username_value, password_value FROM logins;</code>. The plaintext password can then be obtained by passing the encrypted credentials to the Windows API function <code>CryptUnprotectData</code>, which uses the victim's cached logon credentials as the decryption key. (Citation: Microsoft CryptUnprotectData April 2018)

Adversaries have executed similar procedures for common web browsers such as FireFox, Safari, Edge, etc. (Citation: Proofpoint Vega Credential Stealer May 2018)(Citation: FireEye HawkEye Malware July 2017)

Adversaries may also acquire credentials by searching web browser process memory for patterns that commonly match credentials.(Citation: GitHub Mimikittenz July 2016)

After acquiring credentials from web browsers, adversaries may attempt to recycle the credentials across different systems and/or accounts in order to expand access. This can result in significantly furthering an adversary's objective in cases where credentials gained from web browsers overlap with privileged accounts (e.g. domain administrator).

Data from Cloud Storage - T1530

Adversaries may access data from cloud storage.

Many IaaS providers offer solutions for online data object storage such as Amazon S3, Azure Storage, and Google Cloud Storage. Similarly, SaaS enterprise platforms such as Office 365 and Google Workspace provide cloud-based document storage to users through services such as OneDrive and Google Drive, while SaaS application providers such as Slack, Confluence, Salesforce, and Dropbox may provide cloud storage solutions as a peripheral or primary use case of their platform.

In some cases, as with IaaS-based cloud storage, there exists no overarching application (such as SQL or Elasticsearch) with which to interact with the stored objects: instead, data from these solutions is retrieved directly though the [Cloud API](https://attack.mitre.org/techniques/T1059/009). In SaaS applications, adversaries may be able to collect this data directly from APIs or backend cloud storage objects, rather than through their front-end application or interface (i.e., [Data from Information Repositories](https://attack.mitre.org/techniques/T1213)).

Adversaries may collect sensitive data from these cloud storage solutions. Providers typically offer security guides to help end users configure systems, though misconfigurations are a common problem.(Citation: Amazon S3 Security, 2019)(Citation: Microsoft Azure Storage Security, 2019)(Citation: Google Cloud Storage Best Practices, 2019) There have been numerous incidents where cloud storage has been improperly secured, typically by unintentionally allowing public access to unauthenticated users, overly-broad access by all users, or even access for any anonymous person outside the control of the Identity Access Management system without even needing basic user permissions.

This open access may expose various types of sensitive data, such as credit cards, personally identifiable information, or medical records.(Citation: Trend Micro S3 Exposed PII, 2017)(Citation: Wired Magecart S3 Buckets, 2019)(Citation: HIPAA Journal S3 Breach, 2017)(Citation: Rclone-mega-extortion_05_2021)

Adversaries may also obtain then abuse leaked credentials from source repositories, logs, or other means as a way to gain access to cloud storage objects.

Indicator Removal on Host - T1630

Adversaries may delete, alter, or hide generated artifacts on a device, including files, jailbreak status, or the malicious application itself. These actions may interfere with event collection, reporting, or other notifications used to detect intrusion activity. This may compromise the integrity of mobile security solutions by causing notable events or information to go unreported.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal on Host - T1630"*

File and Directory Discovery - T1083

Adversaries may enumerate files and directories or may search in specific locations of a host or network share for certain information within a file system. Adversaries may use the information from [File and Directory Discovery](https://attack.mitre.org/techniques/T1083) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Many command shell utilities can be used to obtain this information. Examples include <code>dir</code>, <code>tree</code>, <code>ls</code>, <code>find</code>, and <code>locate</code>.(Citation: Windows Commands JPCERT) Custom tools may also be used to gather file and directory information and interact with the [Native API](https://attack.mitre.org/techniques/T1106). Adversaries may also leverage a [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) on network devices to gather file and directory information (e.g. <code>dir</code>, <code>show flash</code>, and/or <code>nvram</code>).(Citation: US-CERT-TA18-106A)

Some files and directories may require elevated or specific user permissions to access.

DLL Search Order Hijacking - T1038

Windows systems use a common method to look for required DLLs to load into a program. (Citation: Microsoft DLL Search) Adversaries may take advantage of the Windows DLL search order and programs that ambiguously specify DLLs to gain privilege escalation and persistence.

Adversaries may perform DLL preloading, also called binary planting attacks, (Citation: OWASP Binary Planting) by placing a malicious DLL with the same name as an ambiguously specified DLL in a location that Windows searches before the legitimate DLL. Often this location is the current working directory of the program. Remote DLL preloading attacks occur when a program sets its current directory to a remote location such as a Web share before loading a DLL. (Citation: Microsoft 2269637) Adversaries may use this behavior to cause the program to load a malicious DLL.

Adversaries may also directly modify the way a program loads DLLs by replacing an existing DLL or modifying a .manifest or .local redirection file, directory, or junction to cause the program to load a different DLL to maintain persistence or privilege escalation. (Citation: Microsoft DLL Redirection) (Citation: Microsoft Manifests) (Citation: Mandiant Search Order)

If a search order-vulnerable program is configured to run at a higher privilege level, then the adversary-controlled DLL that is loaded will also be executed at the higher level. In this case, the technique could be used for privilege escalation from user to administrator or SYSTEM or from administrator to SYSTEM, depending on the program.

Programs that fall victim to path hijacking may appear to behave normally because malicious DLLs may be configured to also load the legitimate DLLs they were meant to replace.

Table 8144. Table References

Links
https://attack.mitre.org/techniques/T1440

Exploitation for Privilege Escalation - T1404

Adversaries may exploit software vulnerabilities in order to elevate privileges. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in an application, service, within the operating system software, or kernel itself to execute adversary-controlled code. Security constructions, such as permission levels, will often hinder access to information and use of certain techniques. Adversaries will likely need to perform privilege escalation to include use of software exploitation to circumvent those restrictions.

When initially gaining access to a device, an adversary may be operating within a lower privileged process which will prevent them from accessing certain resources on the system. Vulnerabilities may exist, usually in operating system components and applications running at higher permissions, that can be exploited to gain higher levels of access on the system. This could enable someone to move from unprivileged or user- level permission to root permissions depending on the component that is vulnerable.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation for Privilege Escalation - T1404"*

Table 8145. Table References

Links
https://attack.mitre.org/techniques/T1404
https://pages.nist.gov/mobile-threat-catalogue/application-threats/APP-26.html

File System Permissions Weakness - T1044

Processes may automatically execute specific binaries as part of their functionality or to perform other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself, are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

Services

Manipulation of Windows service binaries is one variation of this technique. Adversaries may replace a legitimate service executable with their own executable to gain persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService). Once the service is started, either directly by the user (if appropriate access is available) or through some other means, such as a system restart if the service starts on bootup, the replaced executable will run instead of the original service executable.

Executable Installers

Another variation of this technique can be performed by taking advantage of a weakness that is common in executable, self-extracting installers. During the installation process, it is common for installers to use a subdirectory within the <code>%TEMP%</code> directory to unpack binaries such as DLLs, EXEs, or other payloads. When installers create subdirectories and files they often do not set appropriate permissions to restrict write access, which allows for execution of untrusted code placed in the subdirectories or overwriting of binaries used in the installation process. This behavior is related to and may take advantage of [DLL Search Order Hijacking](https://attack.mitre.org/techniques/T1038). Some installers may also require elevated privileges that will result in privilege escalation when executing adversary controlled code. This behavior is related to [Bypass User Account Control](https://attack.mitre.org/techniques/T1088). Several examples of this weakness in existing common installers have been reported to software vendors. (Citation: Mozilla Firefox Installer DLL Hijack) (Citation: Seclists Kanthak 7zip Installer)

Obfuscated Files or Information - T1406

Adversaries may attempt to make a payload or file difficult to discover or analyze by encrypting, encoding, or otherwise obfuscating its contents on the device or in transit. This is common behavior that can be used across different platforms and the network to evade defenses.

Payloads may be compressed, archived, or encrypted in order to avoid detection. These payloads may be used during Initial Access or later to mitigate detection. Portions of files can also be encoded to hide the plaintext strings that would otherwise help defenders with discovery. Payloads may also be split into separate, seemingly benign files that only reveal malicious functionality when reassembled.(Citation: Microsoft MalLockerB)

Exfiltration Over Alternative Protocol - T1048

Adversaries may steal data by exfiltrating it over a different protocol than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Alternate protocols include FTP, SMTP, HTTP/S, DNS, SMB, or any other network protocol not being used as the main command and control channel. Adversaries may also opt to encrypt and/or obfuscate these alternate channels.

[Exfiltration Over Alternative Protocol](https://attack.mitre.org/techniques/T1048) can be done using various common operating system utilities such as [Net](https://attack.mitre.org/software/S0039)/SMB or FTP.(Citation: Palo Alto OilRig Oct 2016) On macOS and Linux <code>curl</code> may be used to invoke protocols such as HTTP/S or FTP/S to exfiltrate data from a system.(Citation: 20 macOS Common Tools and Techniques)

Many IaaS and SaaS platforms (such as Microsoft Exchange, Microsoft SharePoint, GitHub, and AWS S3) support the direct download of files, emails, source code, and other sensitive information via the web console or [Cloud API](https://attack.mitre.org/techniques/T1059/009).

System Network Connections Discovery - T1049

Adversaries may attempt to get a listing of network connections to or from the compromised system they are currently accessing or from remote systems by querying for information over the network.

An adversary who gains access to a system that is part of a cloud-based environment may map out Virtual Private Clouds or Virtual Networks in order to determine what systems and services are connected. The actions performed are likely the same types of discovery techniques depending on the operating system, but the resulting information may include details about the networked cloud environment relevant to the adversary's goals. Cloud providers may have different ways in which

their virtual networks operate.(Citation: Amazon AWS VPC Guide)(Citation: Microsoft Azure Virtual Network Overview)(Citation: Google VPC Overview) Similarly, adversaries who gain access to network devices may also perform similar discovery activities to gather information about connected systems and services.

Utilities and commands that acquire this information include [netstat](https://attack.mitre.org/software/S0104), "net use," and "net session" with [Net](https://attack.mitre.org/software/S0039). In Mac and Linux, [netstat](https://attack.mitre.org/software/S0104) and <code>lsof</code> can be used to list current connections. <code>who -a</code> and <code>w</code> can be used to show which users are currently logged in, similar to "net session". Additionally, built-in features native to network devices and [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) may be used (e.g. <code>show ip sockets</code>, <code>show tcp brief</code>).(Citation: US-CERT-TA18-106A) On ESXi servers, the command `esxi network ip connection list` can be used to list active network connections.(Citation: Sygnia ESXi Ransomware 2025)

Use Alternate Authentication Material - T1550

Adversaries may use alternate authentication material, such as password hashes, Kerberos tickets, and application access tokens, in order to move laterally within an environment and bypass normal system access controls.

Authentication processes generally require a valid identity (e.g., username) along with one or more authentication factors (e.g., password, pin, physical smart card, token generator, etc.). Alternate authentication material is legitimately generated by systems after a user or application successfully authenticates by providing a valid identity and the required authentication factor(s). Alternate authentication material may also be generated during the identity creation process.(Citation: NIST Authentication)(Citation: NIST MFA)

Caching alternate authentication material allows the system to verify an identity has successfully authenticated without asking the user to reenter authentication factor(s). Because the alternate authentication must be maintained by the system—either in memory or on disk—it may be at risk of being stolen through [Credential Access](https://attack.mitre.org/tactics/TA0006) techniques. By stealing alternate authentication material, adversaries are able to bypass system access controls and authenticate to systems without knowing the plaintext password or any additional authentication factors.

The tag is: *misp-galaxy:mitre-attack-pattern="Use Alternate Authentication Material - T1550"*

Service Registry Permissions Weakness - T1058

Windows stores local service configuration information in the Registry under <code>HKLM\SYSTEM\CurrentControlSet\Services</code>. The information stored under a service's Registry keys can be manipulated to modify a service's execution parameters through tools such as the service controller, sc.exe, [PowerShell](https://attack.mitre.org/techniques/T1086), or [Reg](https://attack.mitre.org/software/S0075). Access to Registry keys is controlled through Access Control Lists and permissions. (Citation: MSDN Registry Key Security)

If the permissions for users and groups are not properly set and allow access to the Registry keys for a service, then adversaries can change the service binPath/ImagePath to point to a different executable under their control. When the service starts or is restarted, then the adversary-controlled program will execute, allowing the adversary to gain persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService).

Adversaries may also alter Registry keys associated with service failure parameters (such as <code>FailureCommand</code>) that may be executed in an elevated context anytime the service fails or is intentionally corrupted.(Citation: TrustedSignal Service Failure)(Citation: Twitter Service Recovery Nov 2017)

Command and Scripting Interpreter - T1059

Adversaries may abuse command and script interpreters to execute commands, scripts, or binaries. These interfaces and languages provide ways of interacting with computer systems and are a common feature across many different platforms. Most systems come with some built-in command-line interface and scripting capabilities, for example, macOS and Linux distributions include some flavor of [Unix Shell](https://attack.mitre.org/techniques/T1059/004) while Windows installations include the [Windows Command Shell](https://attack.mitre.org/techniques/T1059/003) and [PowerShell](https://attack.mitre.org/techniques/T1059/001).

There are also cross-platform interpreters such as [Python](https://attack.mitre.org/techniques/T1059/006), as well as those commonly associated with client applications such as [JavaScript](https://attack.mitre.org/techniques/T1059/007) and [Visual Basic](https://attack.mitre.org/techniques/T1059/005).

Adversaries may abuse these technologies in various ways as a means of executing arbitrary commands. Commands and scripts can be embedded in [Initial Access](https://attack.mitre.org/tactics/TA0001) payloads delivered to victims as lure documents or as secondary payloads downloaded from an existing C2. Adversaries may also execute commands through interactive terminals/shells, as well as utilize various [Remote Services](https://attack.mitre.org/techniques/T1021) in order to achieve remote Execution.(Citation: Powershell Remote Commands)(Citation: Cisco IOS Software Integrity Assurance - Command History)(Citation: Remote Shell Execution in Python)

Gather Victim Network Information - T1590

Adversaries may gather information about the victim's networks that can be used during targeting. Information about networks may include a variety of details, including administrative data (ex: IP ranges, domain names, etc.) as well as specifics regarding its topology and operations.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](https://attack.mitre.org/techniques/T1595) or [Phishing for Information](https://attack.mitre.org/techniques/T1598). Information about networks may also be exposed to adversaries via online or other accessible data sets (ex: [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596)).(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS) Gathering this information may reveal opportunities for

other forms of reconnaissance (ex: [Active Scanning](https://attack.mitre.org/techniques/T1595) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Acquire Infrastructure](https://attack.mitre.org/techniques/T1583) or [Compromise Infrastructure](https://attack.mitre.org/techniques/T1584)), and/or initial access (ex: [Trusted Relationship](https://attack.mitre.org/techniques/T1199)).

Indicator Removal from Tools - T1066

If a malicious tool is detected and quarantined or otherwise curtailed, an adversary may be able to determine why the malicious tool was detected (the indicator), modify the tool by removing the indicator, and use the updated version that is no longer detected by the target's defensive systems or subsequent targets that may use similar systems.

A good example of this is when malware is detected with a file signature and quarantined by anti-virus software. An adversary who can determine that the malware was quarantined because of its file signature may use [Software Packing](https://attack.mitre.org/techniques/T1045) or otherwise modify the file so it has a different signature, and then re-use the malware.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal from Tools - T1066"*

Table 8155. Table References

Links
https://attack.mitre.org/techniques/T1066

Exploitation for Privilege Escalation - T1068

Adversaries may exploit software vulnerabilities in an attempt to elevate privileges. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Security constructs such as permission levels will often hinder access to information and use of certain techniques, so adversaries will likely need to perform privilege escalation to include use of software exploitation to circumvent those restrictions.

When initially gaining access to a system, an adversary may be operating within a lower privileged process which will prevent them from accessing certain resources on the system. Vulnerabilities may exist, usually in operating system components and software commonly running at higher

permissions, that can be exploited to gain higher levels of access on the system. This could enable someone to move from unprivileged or user level permissions to SYSTEM or root permissions depending on the component that is vulnerable. This could also enable an adversary to move from a virtualized environment, such as within a virtual machine or container, onto the underlying host. This may be a necessary step for an adversary compromising an endpoint system that has been properly configured and limits other privilege escalation methods.

Adversaries may bring a signed vulnerable driver onto a compromised machine so that they can exploit the vulnerability to execute code in kernel mode. This process is sometimes referred to as Bring Your Own Vulnerable Driver (BYOVD).(Citation: ESET InvisiMole June 2020)(Citation: Unit42 AcidBox June 2020) Adversaries may include the vulnerable driver with files delivered during Initial Access or download it to a compromised system via [Ingress Tool Transfer](https://attack.mitre.org/techniques/T1105) or [Lateral Tool Transfer](https://attack.mitre.org/techniques/T1570).

Bypass User Account Control - T1088

Windows User Account Control (UAC) allows a program to elevate its privileges to perform a task under administrator-level permissions by prompting the user for confirmation. The impact to the user ranges from denying the operation under high enforcement to allowing the user to perform the action if they are in the local administrators group and click through the prompt or allowing them to enter an administrator password to complete the action. (Citation: TechNet How UAC Works)

If the UAC protection level of a computer is set to anything but the highest level, certain Windows programs are allowed to elevate privileges or execute some elevated COM objects without prompting the user through the UAC notification box. (Citation: TechNet Inside UAC) (Citation: MSDN COM Elevation) An example of this is use of rundll32.exe to load a specifically crafted DLL which loads an auto-elevated COM object and performs a file operation in a protected directory which would typically require elevated access. Malicious software may also be injected into a trusted process to gain elevated privileges without prompting a user. (Citation: Davidson Windows) Adversaries can use these techniques to elevate privileges to administrator if the target process is unprotected.

Many methods have been discovered to bypass UAC. The Github readme page for UACMe contains an extensive list of methods (Citation: Github UACMe) that have been discovered and implemented

within UACMe, but may not be a comprehensive list of bypasses. Additional bypass methods are regularly discovered and some used in the wild, such as:

- <code>eventvwr.exe</code> can auto-elevate and execute a specified binary or script. (Citation: enigma0x3 Fileless UAC Bypass) (Citation: Fortinet Fareit)

Another bypass is possible through some Lateral Movement techniques if credentials for an account with administrator privileges are known, since UAC is a single system security mechanism, and the privilege or integrity of a process running on one system will be unknown on lateral systems and default to high integrity. (Citation: SANS UAC Bypass)

Exploitation for Defense Evasion - T1211

Adversaries may exploit a system or application vulnerability to bypass security features. Exploitation of a vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Vulnerabilities may exist in defensive security software that can be used to disable or circumvent them.

Adversaries may have prior knowledge through reconnaissance that security software exists within an environment or they may perform checks during or shortly after the system is compromised for [Security Software Discovery](https://attack.mitre.org/techniques/T1518/001). The security software will likely be targeted directly for exploitation. There are examples of antivirus software being targeted by persistent threat groups to avoid detection.

There have also been examples of vulnerabilities in public cloud infrastructure of SaaS applications that may bypass defense boundaries (Citation: Salesforce zero-day in facebook phishing attack),

evade security logs (Citation: Bypassing CloudTrail in AWS Service Catalog), or deploy hidden infrastructure.(Citation: GhostToken GCP flaw)

Extra Window Memory Injection - T1181

Before creating a window, graphical Windows-based processes must prescribe to or register a windows class, which stipulate appearance and behavior (via windows procedures, which are functions that handle input/output of data). (Citation: Microsoft Window Classes) Registration of new windows classes can include a request for up to 40 bytes of extra window memory (EWM) to be appended to the allocated memory of each instance of that class. This EWM is intended to store data specific to that window and has specific application programming interface (API) functions to set and get its value. (Citation: Microsoft GetWindowLong function) (Citation: Microsoft SetWindowLong function)

Although small, the EWM is large enough to store a 32-bit pointer and is often used to point to a windows procedure. Malware may possibly utilize this memory location in part of an attack chain that includes writing code to shared sections of the process's memory, placing a pointer to the code in EWM, then invoking execution by returning execution control to the address in the process's EWM.

Execution granted through EWM injection may take place in the address space of a separate live process. Similar to [Process Injection](https://attack.mitre.org/techniques/T1055), this may allow access to both the target process's memory and possibly elevated privileges. Writing payloads to shared sections also avoids the use of highly monitored API calls such as WriteProcessMemory and CreateRemoteThread. (Citation: Elastic Process Injection July 2017) More sophisticated malware samples may also potentially bypass protection mechanisms such as data execution prevention (DEP) by triggering a combination of windows procedures and other system functions that will rewrite the malicious payload inside an executable portion of the target process. (Citation: MalwareTech Power Loader Aug 2013) (Citation: WeLiveSecurity Gapz and Redyms Mar 2013)

Exploitation for Credential Access - T1212

Adversaries may exploit software vulnerabilities in an attempt to collect credentials. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code.

Credentialing and authentication mechanisms may be targeted for exploitation by adversaries as a means to gain access to useful credentials or circumvent the process to gain authenticated access to systems. One example of this is `MS14-068`, which targets Kerberos and can be used to forge Kerberos tickets using domain user permissions.(Citation: Technet MS14-068)(Citation: ADSecurity Detecting Forged Tickets) Another example of this is replay attacks, in which the adversary intercepts data packets sent between parties and then later replays these packets. If services don't properly validate authentication requests, these replayed packets may allow an adversary to impersonate one of the parties and gain unauthorized access or privileges.(Citation: Bugcrowd Replay Attack)(Citation: Comparitech Replay Attack)(Citation: Microsoft Midnight Blizzard Replay Attack)

Such exploitation has been demonstrated in cloud environments as well. For example, adversaries have exploited vulnerabilities in public cloud infrastructure that allowed for unintended authentication token creation and renewal.(Citation: Storm-0558 techniques for unauthorized email access)

Exploitation for credential access may also result in Privilege Escalation depending on the process targeted or credentials obtained.

Component Object Model Hijacking - T1122

The Component Object Model (COM) is a system within Windows to enable interaction between software components through the operating system. (Citation: Microsoft Component Object Model) Adversaries can use this system to insert malicious code that can be executed in place of legitimate software through hijacking the COM references and relationships as a means for persistence. Hijacking a COM object requires a change in the Windows Registry to replace a reference to a legitimate system component which may cause that component to not work when executed. When that system component is executed through normal system operation the adversary's code will be executed instead. (Citation: GDATA COM Hijacking) An adversary is likely to hijack objects that are used frequently enough to maintain a consistent level of persistence, but are unlikely to break noticeable functionality within the system as to avoid system instability that could lead to detection.

Data from Information Repositories - T1213

Adversaries may leverage information repositories to mine valuable information. Information repositories are tools that allow for storage of information, typically to facilitate collaboration or information sharing between users, and can store a wide variety of data that may aid adversaries in further objectives, such as Credential Access, Lateral Movement, or Defense Evasion, or direct access to the target information. Adversaries may also abuse external sharing features to share sensitive documents with recipients outside of the organization (i.e., [Transfer Data to Cloud Account](https://attack.mitre.org/techniques/T1537)).

The following is a brief list of example information that may hold potential value to an adversary and may also be found on an information repository:

- Policies, procedures, and standards
- Physical / logical network diagrams
- System architecture diagrams
- Technical system documentation

- Testing / development credentials (i.e., [Unsecured Credentials](https://attack.mitre.org/techniques/T1552))
- Work / project schedules
- Source code snippets
- Links to network shares and other internal resources
- Contact or other sensitive information about business partners and customers, including personally identifiable information (PII)

Information stored in a repository may vary based on the specific instance or environment. Specific common information repositories include the following:

- Storage services such as IaaS databases, enterprise databases, and more specialized platforms such as customer relationship management (CRM) databases
- Collaboration platforms such as SharePoint, Confluence, and code repositories
- Messaging platforms such as Slack and Microsoft Teams

In some cases, information repositories have been improperly secured, typically by unintentionally allowing for overly-broad access by all users or even public access to unauthenticated users. This is particularly common with cloud-native or cloud-hosted services, such as AWS Relational Database Service (RDS), Redis, or ElasticSearch.(Citation: Mitiga)(Citation: TrendMicro Exposed Redis 2020)(Citation: Cybernews Reuters Leak 2022)

System Network Connections Discovery - T1421

Adversaries may attempt to get a listing of network connections to or from the compromised device they are currently accessing or from remote systems by querying for information over the network.

This is typically accomplished by utilizing device APIs to collect information about nearby

networks, such as Wi-Fi, Bluetooth, and cellular tower connections. On Android, this can be done by querying the respective APIs:

- `WifiInfo` for information about the current Wi-Fi connection, as well as nearby Wi-Fi networks. Querying the `WiFiInfo` API requires the application to hold the `ACCESS_FINE_LOCATION` permission.
- `BluetoothAdapter` for information about Bluetooth devices, which also requires the application to hold several permissions granted by the user at runtime.
- For Android versions prior to Q, applications can use the `TelephonyManager.getNeighboringCellInfo()` method. For Q and later, applications can use the `TelephonyManager.getAllCellInfo()` method. Both methods require the application hold the `ACCESS_FINE_LOCATION` permission.

Kernel Modules and Extensions - T1215

Loadable Kernel Modules (or LKMs) are pieces of code that can be loaded and unloaded into the kernel upon demand. They extend the functionality of the kernel without the need to reboot the system. For example, one type of module is the device driver, which allows the kernel to access hardware connected to the system. (Citation: Linux Kernel Programming) When used maliciously, Loadable Kernel Modules (LKMs) can be a type of kernel-mode [Rootkit](https://attack.mitre.org/techniques/T1014) that run with the highest operating system privilege (Ring 0). (Citation: Linux Kernel Module Programming Guide) Adversaries can use loadable kernel modules to covertly persist on a system and evade defenses. Examples have been found in the wild and there are some open source projects. (Citation: Volatility Phalanx2) (Citation: CrowdStrike Linux Rootkit) (Citation: GitHub Reptile) (Citation: GitHub Diamorphine)

Common features of LKM based rootkits include: hiding itself, selective hiding of files, processes and network activity, as well as log tampering, providing authenticated backdoors and enabling root access to non-privileged users. (Citation: iDefense Rootkit Overview)

Kernel extensions, also called kext, are used for macOS to load functionality onto a system similar to LKMs for Linux. They are loaded and unloaded through <code>kextload</code> and <code>kextunload</code> commands. Several examples have been found where this can be used. (Citation: RSAC 2015 San Francisco Patrick Wardle) (Citation: Synack Secure Kernel Extension Broken) Examples have been found in the wild. (Citation: Securelist Ventir)

Build Image on Host - T1612

Adversaries may build a container image directly on a host to bypass defenses that monitor for the retrieval of malicious images from a public registry. A remote <code>build</code> request may be sent to the Docker API that includes a Dockerfile that pulls a vanilla base image, such as alpine, from a public or local registry and then builds a custom image upon it.(Citation: Docker Build Image)

An adversary may take advantage of that <code>build</code> API to build a custom image on the host that includes malware downloaded from their C2 server, and then they may utilize [Deploy Container](https://attack.mitre.org/techniques/T1610) using that custom image.(Citation: Aqua Build Images on Hosts)(Citation: Aqua Security Cloud Native Threat Report June 2021) If the base image is pulled from a public registry, defenses will likely not detect the image as malicious since it's a vanilla image. If the base image already resides in a local registry, the pull may be considered even less suspicious since the image is already in the environment.

Obfuscate or encrypt code - T1319

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](http://attack.mitre.org/matrices/enterprise/pre/) matrix for its replacement. The prior content of this page has been preserved [here](https://attack.mitre.org/versions/v7/techniques/T1319).

Obfuscation is the act of creating code that is more difficult to understand. Encoding transforms the code using a publicly available format. Encryption transforms the code such that it requires a key to reverse the encryption. (Citation: CylanceOpCleaver)

Elevated Execution with Prompt - T1514

Adversaries may leverage the AuthorizationExecuteWithPrivileges API to escalate privileges by prompting the user for credentials.(Citation: AppleDocs AuthorizationExecuteWithPrivileges) The purpose of this API is to give application developers an easy way to perform operations with root privileges, such as for application installation or updating. This API does not validate that the program requesting root privileges comes from a reputable source or has been maliciously modified. Although this API is deprecated, it still fully functions in the latest releases of macOS. When calling this API, the user will be prompted to enter their credentials but no checks on the origin or integrity of the program are made. The program calling the API may also load world writable files which can be modified to perform malicious behavior with elevated privileges.

Adversaries may abuse AuthorizationExecuteWithPrivileges to obtain root privileges in order to install malicious software on victims and install persistence mechanisms.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019)(Citation: OSX Coldroot RAT) This technique may be combined with [Masquerading](https://attack.mitre.org/techniques/T1036) to trick the user into granting escalated privileges to malicious code.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019) This technique has also been shown to work by modifying legitimate programs present on the machine that make use of this API.(Citation: Death by 1000 installers; it's all broken!)

Data Encrypted for Impact - T1471

An adversary may encrypt files stored on a mobile device to prevent the user from accessing them. This may be done in order to extract monetary compensation from a victim in exchange for decryption or a decryption key (ransomware) or to render data permanently inaccessible in cases where the key is not saved or transmitted.

The tag is: *misp-galaxy:mitre-attack-pattern="Data Encrypted for Impact - T1471"*

Hidden Files and Directories - T1158

To prevent normal users from accidentally changing special files on a system, most operating systems have the concept of a ‘hidden’ file. These files don’t show up when a user browses the file system with a GUI or when using normal commands on the command line. Users must explicitly ask to show the hidden files either via a series of Graphical User Interface (GUI) prompts or with command line switches (<code>dir /a</code> for Windows and <code>ls –a</code> for Linux and macOS).

Adversaries can use this to their advantage to hide files and folders anywhere on the system for persistence and evading a typical user or system analysis that does not incorporate investigation of hidden files.

Windows

Users can mark specific files as hidden by using the attrib.exe binary. Simply do <code>attrib +h filename</code> to mark a file or folder as hidden. Similarly, the “+s” marks a file as a system file and the “+r” flag marks the file as read only. Like most windows binaries, the attrib.exe binary provides the ability to apply these changes recursively “/S”.

Linux/Mac

Users can mark specific files as hidden simply by putting a “.” as the first character in the file or

folder name (Citation: Sofacy Komplex Trojan) (Citation: Antiquated Mac Malware). Files and folder that start with a period, '.', are by default hidden from being viewed in the Finder application and standard command-line utilities like "ls". Users must specifically change settings to have these files viewable. For command line usages, there is typically a flag to see all files (including hidden ones). To view these files in the Finder Application, the following command must be executed: <code>defaults write com.apple.finder AppleShowAllFiles YES</code>, and then relaunch the Finder Application.

Mac

Files on macOS can be marked with the UF_HIDDEN flag which prevents them from being seen in Finder.app, but still allows them to be seen in Terminal.app (Citation: WireLurker). Many applications create these hidden files and folders to store information so that it doesn't clutter up the user's workspace. For example, SSH utilities create a .ssh folder that's hidden and contains the user's known hosts and keys.

Gather Victim Org Information - T1591

Adversaries may gather information about the victim's organization that can be used during targeting. Information about an organization may include a variety of details, including the names of divisions/departments, specifics of business operations, as well as the roles and responsibilities of key employees.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](https://attack.mitre.org/techniques/T1598). Information about an organization may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](https://attack.mitre.org/techniques/T1593/001) or [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594)).(Citation: ThreatPost Broadvoice Leak)(Citation: SEC EDGAR Search) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](https://attack.mitre.org/techniques/T1598) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Establish Accounts](https://attack.mitre.org/techniques/T1585) or [Compromise Accounts](https://attack.mitre.org/techniques/T1586)), and/or initial access (ex: [Phishing](https://attack.mitre.org/techniques/T1566) or [Trusted Relationship](https://attack.mitre.org/techniques/T1199)).

Search Threat Vendor Data - T1681

Threat actors may seek information/indicators from closed or open threat intelligence sources gathered about their own campaigns, as well as those conducted by other adversaries that may align with their target industries, capabilities/objectives, or other operational concerns. These reports may include descriptions of behavior, detailed breakdowns of attacks, atomic indicators such as malware hashes or IP addresses, timelines of a group's activity, and more. Adversaries may change their behavior when planning their future operations.

Adversaries have been observed replacing atomic indicators mentioned in blog posts in under a week.(Citation: Google Cloud Threat Intelligence VMWare ESXi Zero-Day 2023) Adversaries have also been seen searching for their own domain names in threat vendor data and then taking them down, likely to avoid seizure or further investigation.(Citation: Sentinel One Contagious Interview ClickFix September 2025)

This technique is distinct from [Threat Intel Vendors](https://attack.mitre.org/techniques/T1597/001) in that it describes threat actors performing reconnaissance on their own activity, not in search of victim information.

Cloud Storage Object Discovery - T1619

Adversaries may enumerate objects in cloud storage infrastructure. Adversaries may use this information during automated discovery to shape follow-on behaviors, including requesting all or specific objects from cloud storage. Similar to [File and Directory Discovery](https://attack.mitre.org/techniques/T1083) on a local host, after identifying available storage services (i.e. [Cloud Infrastructure Discovery](https://attack.mitre.org/techniques/T1580)) adversaries may access the contents/objects stored in cloud infrastructure.

Cloud service providers offer APIs allowing users to enumerate objects stored within cloud storage. Examples include ListObjectsV2 in AWS (Citation: ListObjectsV2) and List Blobs in Azure(Citation: List Blobs) .

System Network Configuration Discovery - T1422

Adversaries may look for details about the network configuration and settings, such as IP and/or MAC addresses, of devices they access or through information discovery of remote systems.

Adversaries may use the information from [System Network Configuration Discovery](https://attack.mitre.org/techniques/T1422) during automated discovery to shape follow-on behaviors, including determining certain access within the target network and what actions to do next.

On Android, details of onboard network interfaces are accessible to apps through the `java.net.NetworkInterface` class.(Citation: NetworkInterface) Previously, the Android `TelephonyManager` class could be used to gather telephony-related device identifiers, information such as the IMSI, IMEI, and phone number. However, starting with Android 10, only preloaded, carrier, the default SMS, or device and profile owner applications can access the telephony-related device identifiers.(Citation: TelephonyManager)

On iOS, gathering network configuration information is not possible without root access.

Adversaries may use the information from [System Network Configuration Discovery](https://attack.mitre.org/techniques/T1422) during automated discovery to shape follow-on behaviors, including determining certain access within the target network and what actions to do next.

The tag is: *misp-galaxy:mitre-attack-pattern="System Network Configuration Discovery - T1422"*

Cloud Instance Metadata API - T1522

Adversaries may attempt to access the Cloud Instance Metadata API to collect credentials and other sensitive data.

Most cloud service providers support a Cloud Instance Metadata API which is a service provided to running virtual instances that allows applications to access information about the running virtual instance. Available information generally includes name, security group, and additional metadata including sensitive data such as credentials and UserData scripts that may contain additional secrets. The Instance Metadata API is provided as a convenience to assist in managing applications and is accessible by anyone who can access the instance.(Citation: AWS Instance Metadata API)

If adversaries have a presence on the running virtual instance, they may query the Instance Metadata API directly to identify credentials that grant access to additional resources. Additionally, attackers may exploit a Server-Side Request Forgery (SSRF) vulnerability in a public facing web proxy that allows the attacker to gain access to the sensitive information via a request to the Instance Metadata API.(Citation: RedLock Instance Metadata API 2018)

The de facto standard across cloud service providers is to host the Instance Metadata API at <code>http[:]//169.254.169.254</code>.

The tag is: *misp-galaxy:mitre-attack-pattern="Cloud Instance Metadata API - T1522"*

Command and Scripting Interpreter - T1623

Adversaries may abuse command and script interpreters to execute commands, scripts, or binaries. These interfaces and languages provide ways of interacting with computer systems and are a common feature across many different platforms. Most systems come with some built-in command-line interface and scripting capabilities, for example, Android is a UNIX-like OS and includes a basic [Unix Shell](https://attack.mitre.org/techniques/T1623/001) that can be accessed via the Android Debug Bridge (ADB) or Java's `Runtime` package.

Adversaries may abuse these technologies in various ways as a means of executing arbitrary commands. Commands and scripts can be embedded in [Initial Access](https://attack.mitre.org/tactics/TA0027) payloads delivered to victims as lure documents or as secondary payloads downloaded from an existing C2. Adversaries may also execute commands through interactive terminals/shells.

https://attack.mitre.org/techniques/T1274

Exploitation of Remote Services - T1428

Adversaries may exploit remote services of enterprise servers, workstations, or other resources to gain unauthorized access to internal systems once inside of a network. Adversaries may exploit remote services by taking advantage of a mobile device's access to an internal enterprise network through local connectivity or through a Virtual Private Network (VPN). Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. A common goal for post-compromise exploitation of remote services is for lateral movement to enable access to a remote system.

An adversary may need to determine if the remote system is in a vulnerable state, which may be done through [Network Service Scanning](https://attack.mitre.org/techniques/T1423) or other Discovery methods. These look for common, vulnerable software that may be deployed in the network, the lack of certain patches that may indicate vulnerabilities, or security software that may be used to detect or contain remote exploitation. Servers are likely a high value target for lateral movement exploitation, but endpoint systems may also be at risk if they provide an advantage or access to additional resources.

Depending on the permissions level of the vulnerable remote service, an adversary may achieve [Exploitation for Privilege Escalation](https://attack.mitre.org/techniques/T1404) as a result of lateral movement exploitation as well.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation of Remote Services - T1428"*

Identify web defensive services - T1256

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](http://attack.mitre.org/matrices/enterprise/pre/) matrix for its replacement. The prior content of this page has been preserved [here](https://attack.mitre.org/versions/v7/techniques/T1256).

An adversary can attempt to identify web defensive services as [CloudFlare](https://www.cloudflare.com), [IPBan](https://github.com/jjxtra/Windows-IP-Ban-Service), and [Snort](https://www.snort.org). This may be done by passively detecting services, like [CloudFlare](https://www.cloudflare.com) routing, or actively, such as by purposefully tripping security defenses. (Citation: NMAP WAF NSE)

The tag is: *misp-galaxy:mitre-attack-pattern="Identify web defensive services - T1256"*

Table 8195. Table References

Links

https://attack.mitre.org/techniques/T1256

Steal Application Access Token - T1528

Adversaries can steal application access tokens as a means of acquiring credentials to access remote systems and resources.

Application access tokens are used to make authorized API requests on behalf of a user or service and are commonly used as a way to access resources in cloud and container-based applications and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019) Adversaries who steal account API tokens in cloud and containerized environments may be able to access data and perform actions with the permissions of these accounts, which can lead to privilege escalation and further compromise of the environment.

For example, in Kubernetes environments, processes running inside a container may communicate with the Kubernetes API server using service account tokens. If a container is compromised, an adversary may be able to steal the container's token and thereby gain access to Kubernetes API commands.(Citation: Kubernetes Service Accounts)

Similarly, instances within continuous-development / continuous-integration (CI/CD) pipelines will often use API tokens to authenticate to other services for testing and deployment.(Citation: Cider Security Top 10 CICD Security Risks) If these pipelines are compromised, adversaries may be able to steal these tokens and leverage their privileges.

In Azure, an adversary who compromises a resource with an attached Managed Identity, such as an Azure VM, can request short-lived tokens through the Azure Instance Metadata Service (IMDS). These tokens can then facilitate unauthorized actions or further access to other Azure services, bypassing typical credential-based authentication.(Citation: Entra Managed Identities 2025)(Citation: SpecterOps Managed Identity 2022)

Token theft can also occur through social engineering, in which case user action may be required to grant access. OAuth is one commonly implemented framework that issues tokens to users for access to systems. An application desiring access to cloud-based services or protected APIs can gain entry using OAuth 2.0 through a variety of authorization protocols. An example commonly-used sequence is Microsoft's Authorization Code Grant flow.(Citation: Microsoft Identity Platform Protocols May 2019)(Citation: Microsoft - OAuth Code Authorization flow - June 2019) An OAuth access token enables a third-party application to interact with resources containing user data in the ways requested by the application without obtaining user credentials.

Adversaries can leverage OAuth authorization by constructing a malicious application designed to be granted access to resources with the target user's OAuth token.(Citation: Amnesty OAuth Phishing Attacks, August 2019)(Citation: Trend Micro Pawn Storm OAuth 2017) The adversary will need to complete registration of their application with the authorization server, for example Microsoft Identity Platform using Azure Portal, the Visual Studio IDE, the command-line interface, PowerShell, or REST API calls.(Citation: Microsoft - Azure AD App Registration - May 2019) Then, they can send a [Spearphishing Link](https://attack.mitre.org/techniques/T1566/002) to the target user to entice them to grant access to the application. Once the OAuth access token is granted, the application can gain potentially long-term access to features of the user account through

[Application Access Token](https://attack.mitre.org/techniques/T1550/001).(Citation: Microsoft - Azure AD Identity Tokens - Aug 2019)

Application access tokens may function within a limited lifetime, limiting how long an adversary can utilize the stolen token. However, in some cases, adversaries can also steal application refresh tokens(Citation: Auth0 Understanding Refresh Tokens), allowing them to obtain new access tokens without prompting the user.

The tag is: *misp-galaxy:mitre-attack-pattern="Steal Application Access Token - T1528"*

Gather Victim Host Information - T1592

Adversaries may gather information about the victim's hosts that can be used during targeting. Information about hosts may include a variety of details, including administrative data (ex: name, assigned IP, functionality, etc.) as well as specifics regarding its configuration (ex: operating system, language, etc.).

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](https://attack.mitre.org/techniques/T1595) or [Phishing for Information](https://attack.mitre.org/techniques/T1598). Adversaries may also compromise sites then include malicious content designed to collect host information from visitors.(Citation: ATT ScanBox) Information about hosts may also be exposed to adversaries via online or other accessible

data sets (ex: [Social Media](https://attack.mitre.org/techniques/T1593/001) or [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594)). Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593) or [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596)), establishing operational resources (ex: [Develop Capabilities](https://attack.mitre.org/techniques/T1587) or [Obtain Capabilities](https://attack.mitre.org/techniques/T1588)), and/or initial access (ex: [Supply Chain Compromise](https://attack.mitre.org/techniques/T1195) or [External Remote Services](https://attack.mitre.org/techniques/T1133)).

Adversaries may also gather victim host information via User-Agent HTTP headers, which are sent to a server to identify the application, operating system, vendor, and/or version of the requesting user agent. This can be used to inform the adversary's follow-on action. For example, adversaries may check user agents for the requesting operating system, then only serve malware for target operating systems while ignoring others.(Citation: TrellixQakbot)

Abuse Elevation Control Mechanism - T1626

Adversaries may circumvent mechanisms designed to control elevated privileges to gain higher-level permissions. Most modern systems contain native elevation control mechanisms that are intended to limit privileges that a user can gain on a machine. Authorization has to be granted to specific users in order to perform tasks that are designated as higher risk. An adversary can use several methods to take advantage of built-in control mechanisms in order to escalate privileges on a system.

Data from Local System - T1533

Adversaries may search local system sources, such as file systems or local databases, to find files of interest and sensitive data prior to exfiltration.

Access to local system data, which includes information stored by the operating system, often requires escalated privileges. Examples of local system data include authentication tokens, the device keyboard cache, Wi-Fi passwords, and photos. On Android, adversaries may also attempt to access files from external storage which may require additional storage-related permissions.

Generate Traffic from Victim - T1643

Adversaries may generate outbound traffic from devices. This is typically performed to manipulate external outcomes, such as to achieve carrier billing fraud or to manipulate app store rankings or ratings. Outbound traffic is typically generated as SMS messages or general web traffic, but may take other forms as well.

If done via SMS messages, Android apps must hold the `SEND_SMS` permission. Additionally, sending an SMS message requires user consent if the recipient is a premium number. Applications cannot send SMS messages on iOS

Steal Application Access Token - T1635

Adversaries can steal user application access tokens as a means of acquiring credentials to access remote systems and resources. This can occur through social engineering or URI hijacking and typically requires user action to grant access, such as through a system “Open With” dialogue.

Application access tokens are used to make authorized API requests on behalf of a user and are commonly used as a way to access resources in cloud-based applications and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019) OAuth is one commonly implemented framework used to issue tokens to users for access to systems. An application desiring access to cloud-based services or protected APIs can gain entry through OAuth 2.0 using a variety of authorization protocols. An example of a commonly-used sequence is Microsoft’s Authorization Code Grant flow.(Citation: Microsoft Identity Platform Protocols May 2019)(Citation: Microsoft - OAuth Code Authorization flow - June 2019) An OAuth access token enables a third-party application to interact with resources containing user data in the ways requested without requiring user credentials.

Remote Service Session Hijacking - T1563

Adversaries may take control of preexisting sessions with remote services to move laterally in an environment. Users may use valid credentials to log into a service specifically designed to accept remote connections, such as telnet, SSH, and RDP. When a user logs into a service, a session will be established that will allow them to maintain a continuous interaction with that service.

Adversaries may commandeer these sessions to carry out actions on remote systems. [Remote Service Session Hijacking](https://attack.mitre.org/techniques/T1563) differs from use of [Remote Services](https://attack.mitre.org/techniques/T1021) because it hijacks an existing session rather than creating a new session using [Valid Accounts](https://attack.mitre.org/techniques/T1078).(Citation: RDP Hijacking Medium)(Citation: Breach Post-mortem SSH Hijack)

Steal Web Session Cookie - T1539

An adversary may steal web application or service session cookies and use them to gain access to web applications or Internet services as an authenticated user without needing credentials. Web applications and services often use session cookies as an authentication token after a user has authenticated to a website.

Cookies are often valid for an extended period of time, even if the web application is not actively used. Cookies can be found on disk, in the process memory of the browser, and in network traffic to remote systems. Additionally, other applications on the targets machine might store sensitive authentication cookies in memory (e.g. apps which authenticate to cloud services). Session cookies can be used to bypasses some multi-factor authentication protocols.(Citation: Pass The Cookie)

There are several examples of malware targeting cookies from web browsers on the local system.(Citation: Kaspersky TajMahal April 2019)(Citation: Unit 42 Mac Crypto Cookies January 2019) Adversaries may also steal cookies by injecting malicious JavaScript content into websites or relying on [User Execution](https://attack.mitre.org/techniques/T1204) by tricking victims into

running malicious JavaScript in their browser.(Citation: Talos Roblox Scam 2023)(Citation: Krebs Discord Bookmarks 2023)

There are also open source frameworks such as `Evilginx2` and `Muraena` that can gather session cookies through a malicious proxy (e.g., [Adversary-in-the-Middle](https://attack.mitre.org/techniques/T1557)) that can be set up by an adversary and used in phishing campaigns.(Citation: Github evilginx2)(Citation: GitHub Mauraena)

After an adversary acquires a valid cookie, they can then perform a [Web Session Cookie](https://attack.mitre.org/techniques/T1550/004) technique to login to the corresponding web application.

Masquerade as Legitimate Application - T1444

An adversary could distribute developed malware by masquerading the malware as a legitimate application. This can be done in two different ways: by embedding the malware in a legitimate application, or by pretending to be a legitimate application.

Embedding the malware in a legitimate application is done by downloading the application, disassembling it, adding the malicious code, and then re-assembling it.(Citation: Zhou) The app would appear to be the original app, but would contain additional malicious functionality. The adversary could then publish the malicious application to app stores or use another delivery method.

Pretending to be a legitimate application relies heavily on lack of scrutinization by the user. Typically, a malicious app pretending to be a legitimate one will have many similar details as the

legitimate one, such as name, icon, and description.(Citation: Palo Alto HenBox)

Malicious applications may also masquerade as legitimate applications when requesting access to the accessibility service in order to appear as legitimate to the user, increasing the likelihood that the access will be granted.

The tag is: *misp-galaxy:mitre-attack-pattern="Masquerade as Legitimate Application - T1444"*

Out of Band Data - T1644

Adversaries may communicate with compromised devices using out of band data streams. This could be done for a variety of reasons, including evading network traffic monitoring, as a backup method of command and control, or for data exfiltration if the device is not connected to any Internet-providing networks (i.e. cellular or Wi-Fi). Several out of band data streams exist, such as SMS messages, NFC, and Bluetooth.

On Android, applications can read push notifications to capture content from SMS messages, or other out of band data streams. This requires that the user manually grant notification access to the application via the settings menu. However, the application could launch an Intent to take the user directly there.

On iOS, there is no way to programmatically read push notifications.

The tag is: *misp-galaxy:mitre-attack-pattern="Out of Band Data - T1644"*

Table 8213. Table References

Links
https://attack.mitre.org/techniques/T1644

Network Denial of Service - T1464

Adversaries may perform Network Denial of Service (DoS) attacks to degrade or block the availability of targeted resources to users. Network DoS can be performed by exhausting the network bandwidth that services rely on, or by jamming the signal going to or coming from devices.

A Network DoS will occur when an adversary is able to jam radio signals (e.g. Wi-Fi, cellular, GPS)

around a device to prevent it from communicating. For example, to jam cellular signal, an adversary may use a handheld signal jammer, which jam devices within the jammer's operational range.(Citation: NIST-SP800187)

Usage of cellular jamming has been documented in several arrests reported in the news.(Citation: CNET-Celljammer)(Citation: NYTimes-Celljam)(Citation: Digitaltrends-Celljam)(Citation: Arstechnica-Celljam)

Compromise Host Software Binary - T1554

Adversaries may modify host software binaries to establish persistent access to systems. Software binaries/executables provide a wide range of system commands or services, programs, and libraries. Common software binaries are SSH clients, FTP clients, email clients, web browsers, and many other user or server applications.

Adversaries may establish persistence though modifications to host software binaries. For example, an adversary may replace or otherwise infect a legitimate application binary (or support files) with a backdoor. Since these binaries may be routinely executed by applications or the user, the adversary can leverage this for persistent access to the host. An adversary may also modify a software binary such as an SSH client in order to persistently collect credentials during logins (i.e., [Modify Authentication Process](https://attack.mitre.org/techniques/T1556)).(Citation: Google Cloud Mandiant UNC3886 2024)

An adversary may also modify an existing binary by patching in malicious functionality (e.g., IAT Hooking/Entry point patching)(Citation: Unit42 Banking Trojans Hooking 2022) prior to the binary's legitimate execution. For example, an adversary may modify the entry point of a binary to point to malicious code patched in by the adversary before resuming normal execution flow.(Citation: ESET

FontOnLake Analysis 2021)

After modifying a binary, an adversary may attempt to [Impair Defenses](https://attack.mitre.org/techniques/T1562) by preventing it from updating (e.g., via the `yum-versionlock` command or `versionlock.list` file in Linux systems that use the yum package manager).(Citation: Google Cloud Mandiant UNC3886 2024)

Compromise Client Software Binary - T1645

Adversaries may modify system software binaries to establish persistent access to devices. System software binaries are used by the underlying operating system and users over adb or terminal emulators.

Adversaries may make modifications to client software binaries to carry out malicious tasks when those binaries are executed. For example, malware may come with a pre-compiled malicious binary intended to overwrite the genuine one on the device. Since these binaries may be routinely executed by the system or user, the adversary can leverage this for persistent access to the device.

Exploitation for Initial Access - T1664

Adversaries may exploit software vulnerabilities to gain initial access to a mobile device.

This can be accomplished in a variety of ways. Vulnerabilities may be present in the applications, the services, the underlying operating system, or the kernel itself. Several well-known mobile device exploits exist, including FORCEDENTRY, StageFright, and BlueBorne. Furthermore, some exploits may be possible to exploit without any user interaction (i.e. zero-click exploits, see [Exploitation for Client Execution](https://attack.mitre.org/techniques/T1658)), making them particularly dangerous. Mobile operating system vendors are typically very quick to patch such critical bugs, ensuring only a small window where they can be exploited.

https://pages.nist.gov/mobile-threat-catalogue/cellular-threats/CEL-7.html

Data Encrypted for Impact - T1486

Adversaries may encrypt data on target systems or on large numbers of systems in a network to interrupt availability to system and network resources. They can attempt to render stored data inaccessible by encrypting files or data on local and remote drives and withholding access to a decryption key. This may be done in order to extract monetary compensation from a victim in exchange for decryption or a decryption key (ransomware) or to render data permanently inaccessible in cases where the key is not saved or transmitted.(Citation: US-CERT Ransomware 2016)(Citation: FireEye WannaCry 2017)(Citation: US-CERT NotPetya 2017)(Citation: US-CERT SamSam 2018)

In the case of ransomware, it is typical that common user files like Office documents, PDFs, images, videos, audio, text, and source code files will be encrypted (and often renamed and/or tagged with specific file markers). Adversaries may need to first employ other behaviors, such as [File and Directory Permissions Modification](https://attack.mitre.org/techniques/T1222) or [System Shutdown/Reboot](https://attack.mitre.org/techniques/T1529), in order to unlock and/or gain access to manipulate these files.(Citation: CarbonBlack Conti July 2020) In some cases, adversaries may encrypt critical system files, disk partitions, and the MBR.(Citation: US-CERT NotPetya 2017) Adversaries may also encrypt virtual machines hosted on ESXi or other hypervisors.(Citation: Crowdstrike Hypervisor Jackpotting Pt 2 2021)

To maximize impact on the target organization, malware designed for encrypting data may have worm-like features to propagate across a network by leveraging other attack techniques like [Valid Accounts](https://attack.mitre.org/techniques/T1078), [OS Credential Dumping](https://attack.mitre.org/techniques/T1003), and [SMB/Windows Admin Shares](https://attack.mitre.org/techniques/T1021/002).(Citation: FireEye WannaCry 2017)(Citation: US-CERT NotPetya 2017) Encryption malware may also leverage [Internal Defacement](https://attack.mitre.org/techniques/T1491/001), such as changing victim wallpapers or ESXi server login messages, or otherwise intimidate victims by sending ransom notes or other messages to connected printers (known as "print bombing").(Citation: NHS Digital Egregor Nov 2020)(Citation: Varonis)

In cloud environments, storage objects within compromised accounts may also be encrypted.(Citation: Rhino S3 Ransomware Part 1) For example, in AWS environments, adversaries may leverage services such as AWS's Server-Side Encryption with Customer Provided Keys (SSE-C) to encrypt data.(Citation: Halcyon AWS Ransomware 2025)

Exploit via Radio Interfaces - T1477

The mobile device may be targeted for exploitation through its interface to cellular networks or other radio interfaces.

Baseband Vulnerability Exploitation

A message sent over a radio interface (typically cellular, but potentially Bluetooth, GPS, NFC, Wi-Fi(Citation: ProjectZero-BroadcomWiFi) or other) to the mobile device could exploit a vulnerability in code running on the device(Citation: Register-BaseStation)(Citation: Weinmann-Baseband).

Malicious SMS Message

An SMS message could contain content designed to exploit vulnerabilities in the SMS parser on the receiving device(Citation: Forbes-iPhoneSMS). An SMS message could also contain a link to a web site containing malicious content designed to exploit the device web browser. Vulnerable SIM cards may be remotely exploited and reprogrammed via SMS messages(Citation: SRLabs-SIMCard).

The tag is: *misp-galaxy:mitre-attack-pattern="Exploit via Radio Interfaces - T1477"*

Network Denial of Service - T1498

Adversaries may perform Network Denial of Service (DoS) attacks to degrade or block the availability of targeted resources to users. Network DoS can be performed by exhausting the network bandwidth services rely on. Example resources include specific websites, email services, DNS, and web-based applications. Adversaries have been observed conducting network DoS attacks for political purposes(Citation: FireEye OpPoisonedHandover February 2016) and to support other malicious activities, including distraction(Citation: FSISAC FraudNetDoS September 2012), hacktivism, and extortion.(Citation: Symantec DDoS October 2014)

A Network DoS will occur when the bandwidth capacity of the network connection to a system is exhausted due to the volume of malicious traffic directed at the resource or the network connections and network devices the resource relies on. For example, an adversary may send 10Gbps of traffic to a server that is hosted by a network with a 1Gbps connection to the internet. This traffic can be generated by a single system or multiple systems spread across the internet, which is commonly referred to as a distributed DoS (DDoS).

To perform Network DoS attacks several aspects apply to multiple methods, including IP address spoofing, and botnets.

Adversaries may use the original IP address of an attacking system, or spoof the source IP address to make the attack traffic more difficult to trace back to the attacking system or to enable reflection. This can increase the difficulty defenders have in defending against the attack by reducing or eliminating the effectiveness of filtering by the source address on network defense devices.

For DoS attacks targeting the hosting system directly, see [Endpoint Denial of Service](https://attack.mitre.org/techniques/T1499).

The tag is: *misp-galaxy:mitre-attack-pattern="Network Denial of Service - T1498"*

Endpoint Denial of Service - T1499

Adversaries may perform Endpoint Denial of Service (DoS) attacks to degrade or block the availability of services to users. Endpoint DoS can be performed by exhausting the system resources those services are hosted on or exploiting the system to cause a persistent crash condition. Example services include websites, email services, DNS, and web-based applications. Adversaries have been observed conducting DoS attacks for political purposes(Citation: FireEye OpPoisonedHandover February 2016) and to support other malicious activities, including distraction(Citation: FSISAC FraudNetDoS September 2012), hacktivism, and extortion.(Citation: Symantec DDoS October 2014)

An Endpoint DoS denies the availability of a service without saturating the network used to provide access to the service. Adversaries can target various layers of the application stack that is hosted on the system used to provide the service. These layers include the Operating Systems (OS), server applications such as web servers, DNS servers, databases, and the (typically web-based) applications that sit on top of them. Attacking each layer requires different techniques that take advantage of bottlenecks that are unique to the respective components. A DoS attack may be generated by a single system or multiple systems spread across the internet, which is commonly referred to as a distributed DoS (DDoS).

To perform DoS attacks against endpoint resources, several aspects apply to multiple methods, including IP address spoofing and botnets.

Adversaries may use the original IP address of an attacking system, or spoof the source IP address to make the attack traffic more difficult to trace back to the attacking system or to enable reflection. This can increase the difficulty defenders have in defending against the attack by reducing or eliminating the effectiveness of filtering by the source address on network defense devices.

Botnets are commonly used to conduct DDoS attacks against networks and services. Large botnets can generate a significant amount of traffic from systems spread across the global internet. Adversaries may have the resources to build out and control their own botnet infrastructure or may rent time on an existing botnet to conduct an attack. In some of the worst cases for DDoS, so many systems are used to generate requests that each one only needs to send out a small amount of traffic to produce enough volume to exhaust the target's resources. In such circumstances, distinguishing DDoS traffic from legitimate clients becomes exceedingly difficult. Botnets have been used in some of the most high-profile DDoS attacks, such as the 2012 series of incidents that targeted major US banks.(Citation: USNYAG IranianBotnet March 2016)

In cases where traffic manipulation is used, there may be points in the global network (such as high traffic gateway routers) where packets can be altered and cause legitimate clients to execute code that directs network packets toward a target in high volume. This type of capability was previously used for the purposes of web censorship where client HTTP traffic was modified to include a reference to JavaScript that generated the DDoS code to overwhelm target web servers.(Citation: ArsTechnica Great Firewall of China)

For attacks attempting to saturate the providing network, see [Network Denial of Service](https://attack.mitre.org/techniques/T1498).

Credentials from Password Stores - T1555

Adversaries may search for common password storage locations to obtain user credentials.(Citation: F-Secure The Dukes) Passwords are stored in several places on a system, depending on the operating system or application holding the credentials. There are also specific applications and services that store passwords to make them easier for users to manage and maintain, such as password managers and cloud secrets vaults. Once credentials are obtained, they can be used to perform lateral movement and access restricted information.

Exfiltration Over Web Service - T1567

Adversaries may use an existing, legitimate external Web service to exfiltrate data rather than their primary command and control channel. Popular Web services acting as an exfiltration mechanism may give a significant amount of cover due to the likelihood that hosts within a network are

already communicating with them prior to compromise. Firewall rules may also already exist to permit traffic to these services.

Web service providers also commonly use SSL/TLS encryption, giving adversaries an added level of protection.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration Over Web Service - T1567"*

Table 8227. Table References

https://attack.mitre.org/techniques/T1567

Exploitation for Client Execution - T1658

Adversaries may exploit software vulnerabilities in client applications to execute code. Vulnerabilities can exist in software due to insecure coding practices that can lead to unanticipated behavior. Adversaries may take advantage of certain vulnerabilities through targeted exploitation for the purpose of arbitrary code execution. Oftentimes the most valuable exploits to an offensive toolkit are those that can be used to obtain code execution on a remote system because they can be used to gain access to that system. Users will expect to see files related to the applications they commonly used to do work, so they are a useful target for exploit research and development because of their high utility.

Adversaries may use device-based zero-click exploits for code execution. These exploits are powerful because there is no user interaction required for code execution.

SMS/iMessage Delivery

SMS and iMessage in iOS are common targets through [Drive-By Compromise](https://attack.mitre.org/techniques/T1456), [Phishing](https://attack.mitre.org/techniques/T1660), etc. Adversaries may use embed malicious links, files, etc. in SMS messages or iMessages. Mobile devices may be compromised through one-click exploits, where the victim must interact with a text message, or zero-click exploits, where no user interaction is required.

AirDrop

Unique to iOS, AirDrop is a network protocol that allows iOS users to transfer files between iOS devices. Before patches from Apple were released, on iOS 13.4 and earlier, adversaries may force the Apple Wireless Direct Link (AWDL) interface to activate, then exploit a buffer overflow to gain access to the device and run as root without interaction from the user.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation for Client Execution - T1658"*

Table 8228. Table References

https://attack.mitre.org/techniques/T1658

Search Open Technical Databases - T1596

Adversaries may search freely available technical databases for information about victims that can be used during targeting. Information about victims may be available in online databases and repositories, such as registrations of domains/certificates as well as public collections of network data/artifacts gathered from traffic and/or scans.(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS)(Citation: Medium SSL Cert)(Citation: SSLShopper Lookup)(Citation: DigitalShadows CDN)(Citation: Shodan)

Adversaries may search in different open databases depending on what information they seek to gather. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](https://attack.mitre.org/techniques/T1598) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Acquire Infrastructure](https://attack.mitre.org/techniques/T1583) or [Compromise Infrastructure](https://attack.mitre.org/techniques/T1584)), and/or initial access (ex: [External Remote Services](https://attack.mitre.org/techniques/T1133) or [Trusted Relationship](https://attack.mitre.org/techniques/T1199)).

Modify Cloud Compute Infrastructure - T1578

An adversary may attempt to modify a cloud account's compute service infrastructure to evade defenses. A modification to the compute service infrastructure can include the creation, deletion, or modification of one or more components such as compute instances, virtual machines, and snapshots.

Permissions gained from the modification of infrastructure components may bypass restrictions that prevent access to existing infrastructure. Modifying infrastructure components may also allow an adversary to evade detection and remove evidence of their presence.(Citation: Mandiant M-Trends 2020)

The tag is: *misp-galaxy:mitre-attack-pattern="Modify Cloud Compute Infrastructure - T1578"*

Table 8230. Table References

Gather Victim Identity Information - T1589

Adversaries may gather information about the victim's identity that can be used during targeting. Information about identities may include a variety of details, including personal data (ex: employee names, email addresses, security question responses, etc.) as well as sensitive details such as credentials or multi-factor authentication (MFA) configurations.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](https://attack.mitre.org/techniques/T1598). Information about users could also be enumerated via other active means (i.e. [Active Scanning](https://attack.mitre.org/techniques/T1595)) such as probing and analyzing responses from authentication services that may reveal valid usernames in a system or permitted MFA /methods associated with those usernames.(Citation: GrimBlog UsernameEnum)(Citation: Obsidian SSPR Abuse 2023) Information about victims may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](https://attack.mitre.org/techniques/T1593/001) or [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594)).(Citation: OPM Leak)(Citation: Register Deloitte)(Citation: Register Uber)(Citation: Detectify Slack Tokens)(Citation: Forbes GitHub Creds)(Citation: GitHub truffleHog)(Citation: GitHub Gitrob)(Citation: CNET Leaks)

Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593) or [Phishing for Information](https://attack.mitre.org/techniques/T1598)), establishing operational resources (ex: [Compromise Accounts](https://attack.mitre.org/techniques/T1586)), and/or initial access (ex: [Phishing](https://attack.mitre.org/techniques/T1566) or [Valid Accounts](https://attack.mitre.org/techniques/T1078)).

Modify Cloud Resource Hierarchy - T1666

Adversaries may attempt to modify hierarchical structures in infrastructure-as-a-service (IaaS) environments in order to evade defenses.

IaaS environments often group resources into a hierarchy, enabling improved resource management and application of policies to relevant groups. Hierarchical structures differ among cloud providers. For example, in AWS environments, multiple accounts can be grouped under a single organization, while in Azure environments, multiple subscriptions can be grouped under a single management group.(Citation: AWS Organizations)(Citation: Microsoft Azure Resources)

Adversaries may add, delete, or otherwise modify resource groups within an IaaS hierarchy. For example, in Azure environments, an adversary who has gained access to a Global Administrator account may create new subscriptions in which to deploy resources. They may also engage in subscription hijacking by transferring an existing pay-as-you-go subscription from a victim tenant to an adversary-controlled tenant. This will allow the adversary to use the victim's compute resources without generating logs on the victim tenant.(Citation: Microsoft Peach Sandstorm 2023)(Citation: Microsoft Subscription Hijacking 2022)

In AWS environments, adversaries with appropriate permissions in a given account may call the `LeaveOrganization` API, causing the account to be severed from the AWS Organization to which it was tied and removing any Service Control Policies, guardrails, or restrictions imposed upon it by its former Organization. Alternatively, adversaries may call the `CreateAccount` API in order to create a new account within an AWS Organization. This account will use the same payment methods registered to the payment account but may not be subject to existing detections or Service Control Policies.(Citation: AWS RE:Inforce Threat Detection 2024)

AutoHotKey & AutoIT - T1059.010

Adversaries may execute commands and perform malicious tasks using AutoIT and AutoHotKey automation scripts. AutoIT and AutoHotkey (AHK) are scripting languages that enable users to automate Windows tasks. These automation scripts can be used to perform a wide variety of actions, such as clicking on buttons, entering text, and opening and closing programs.(Citation: AutoIT)(Citation: AutoHotKey)

Adversaries may use AHK (`.ahk`) and AutoIT (`.au3`) scripts to execute malicious code on a victim's system. For example, adversaries have used for AHK to execute payloads and other modular malware such as keyloggers. Adversaries have also used custom AHK files containing embedded malware as [Phishing](https://attack.mitre.org/techniques/T1566) payloads.(Citation: Splunk DarkGate)

These scripts may also be compiled into self-contained executable payloads (`.exe`).(Citation: AutoIT)(Citation: AutoHotKey)

SNMP (MIB Dump) - T1602.001

Adversaries may target the Management Information Base (MIB) to collect and/or mine valuable information in a network managed using Simple Network Management Protocol (SNMP).

The MIB is a configuration repository that stores variable information accessible via SNMP in the form of object identifiers (OID). Each OID identifies a variable that can be read or set and permits active management tasks, such as configuration changes, through remote modification of these variables. SNMP can give administrators great insight in their systems, such as, system information, description of hardware, physical location, and software packages(Citation: SANS Information Security Reading Room Securing SNMP Securing SNMP). The MIB may also contain device operational information, including running configuration, routing table, and interface details.

Adversaries may use SNMP queries to collect MIB content directly from SNMP-managed devices in

order to collect network information that allows the adversary to build network maps and facilitate future targeted exploitation.(Citation: US-CERT-TA18-106A)(Citation: Cisco Blog Legacy Device Attacks)

The tag is: *misp-galaxy:mitre-attack-pattern="SNMP (MIB Dump) - T1602.001"*

Logon Script (Windows) - T1037.001

Adversaries may use Windows logon scripts automatically executed at logon initialization to establish persistence. Windows allows logon scripts to be run whenever a specific user or group of users log into a system.(Citation: TechNet Logon Scripts) This is done via adding a path to a script to the <code>HKCU\Environment\UserInitMprLogonScript</code> Registry key.(Citation: Hexacorn Logon Scripts)

Adversaries may use these scripts to maintain persistence on a single system. Depending on the access configuration of the logon scripts, either local credentials or an administrator account may be necessary.

Dynamic-link Library Injection - T1055.001

Adversaries may inject dynamic-link libraries (DLLs) into processes in order to evade process-based defenses as well as possibly elevate privileges. DLL injection is a method of executing arbitrary code in the address space of a separate live process.

DLL injection is commonly performed by writing the path to a DLL in the virtual address space of the target process before loading the DLL by invoking a new thread. The write can be performed with native Windows API calls such as <code>VirtualAllocEx</code> and <code>WriteProcessMemory</code>, then invoked with <code>CreateRemoteThread</code> (which calls the <code>LoadLibrary</code> API responsible for loading the DLL). (Citation: Elastic Process Injection July 2017)

Variations of this method such as reflective DLL injection (writing a self-mapping DLL into a process) and memory module (map DLL when writing into process) overcome the address relocation issue as well as the additional APIs to invoke execution (since these methods load and execute the files in memory by manually preforming the function of <code>LoadLibrary</code>).(Citation: Elastic HuntingNMemory June 2017)(Citation: Elastic Process Injection July 2017)

Another variation of this method, often referred to as Module Stomping/Overloading or DLL Hollowing, may be leveraged to conceal injected code within a process. This method involves loading a legitimate DLL into a remote process then manually overwriting the module's <code>AddressOfEntryPoint</code> before starting a new thread in the target process.(Citation: Module Stomping for Shellcode Injection) This variation allows attackers to hide malicious injected code by potentially backing its execution with a legitimate DLL file on disk.(Citation: Hiding Malicious Code with Module Stomping)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via DLL injection may also evade detection from security products since the execution is masked under a legitimate process.

Exploit Public-Facing Application - T1190

Adversaries may attempt to exploit a weakness in an Internet-facing host or system to initially access a network. The weakness in the system can be a software bug, a temporary glitch, or a misconfiguration.

Exploited applications are often websites/web servers, but can also include databases (like SQL), standard services (like SMB or SSH), network device administration and management protocols (like SNMP and Smart Install), and any other system with Internet-accessible open sockets.(Citation: NVD CVE-2016-6662)(Citation: CIS Multiple SMB Vulnerabilities)(Citation: US-CERT TA18-106A Network Infrastructure Devices 2018)(Citation: Cisco Blog Legacy Device Attacks)(Citation: NVD CVE-2014-7169) On ESXi infrastructure, adversaries may exploit exposed OpenSLP services; they may alternatively exploit exposed VMware vCenter servers.(Citation: Recorded Future ESXiArgs Ransomware 2023)(Citation: Ars Technica VMWare Code Execution Vulnerability 2021) Depending on the flaw being exploited, this may also involve [Exploitation for Defense Evasion](https://attack.mitre.org/techniques/T1211) or [Exploitation for Client Execution](https://attack.mitre.org/techniques/T1203).

If an application is hosted on cloud-based infrastructure and/or is containerized, then exploiting it may lead to compromise of the underlying instance or container. This can allow an adversary a path to access the cloud or container APIs (e.g., via the [Cloud Instance Metadata API](https://attack.mitre.org/techniques/T1552/005)), exploit container host access via [Escape to Host](https://attack.mitre.org/techniques/T1611), or take advantage of weak identity and access management policies.

Adversaries may also exploit edge network infrastructure and related appliances, specifically targeting devices that do not support robust host-based defenses.(Citation: Mandiant Fortinet Zero Day)(Citation: Wired Russia Cyberwar)

For websites and databases, the OWASP top 10 and CWE top 25 highlight the most common web-based vulnerabilities.(Citation: OWASP Top 10)(Citation: CWE top 25)

Non-Application Layer Protocol - T1095

Adversaries may use an OSI non-application layer protocol for communication between host and C2 server or among infected hosts within a network. The list of possible protocols is extensive.(Citation: Wikipedia OSI) Specific examples include use of network layer protocols, such as the Internet Control Message Protocol (ICMP), transport layer protocols, such as the User Datagram Protocol (UDP), session layer protocols, such as Socket Secure (SOCKS), as well as redirected/tunneled protocols, such as Serial over LAN (SOL).

ICMP communication between hosts is one example.(Citation: Cisco Synful Knock Evolution) Because ICMP is part of the Internet Protocol Suite, it is required to be implemented by all IP-compatible hosts.(Citation: Microsoft ICMP) However, it is not as commonly monitored as other Internet Protocols such as TCP or UDP and may be used by adversaries to hide communications.

In ESXi environments, adversaries may leverage the Virtual Machine Communication Interface

(VMCI) for communication between guest virtual machines and the ESXi host. This traffic is similar to client-server communications on traditional network sockets but is localized to the physical machine running the ESXi host, meaning it does not traverse external networks (routers, switches). This results in communications that are invisible to external monitoring and standard networking tools like tcpdump, netstat, nmap, and Wireshark. By adding a VMCI backdoor to a compromised ESXi host, adversaries may persistently regain access from any guest VM to the compromised ESXi host's backdoor, regardless of network segmentation or firewall rules in place.(Citation: Google Cloud Threat Intelligence VMWare ESXi Zero-Day 2023)

Multi-Factor Authentication Interception - T1111

Adversaries may target multi-factor authentication (MFA) mechanisms, (i.e., smart cards, token generators, etc.) to gain access to credentials that can be used to access systems, services, and network resources. Use of MFA is recommended and provides a higher level of security than usernames and passwords alone, but organizations should be aware of techniques that could be used to intercept and bypass these security mechanisms.

If a smart card is used for multi-factor authentication, then a keylogger will need to be used to obtain the password associated with a smart card during normal use. With both an inserted card and access to the smart card password, an adversary can connect to a network resource using the infected system to proxy the authentication with the inserted hardware token. (Citation: Mandiant M Trends 2011)

Adversaries may also employ a keylogger to similarly target other hardware tokens, such as RSA SecurID. Capturing token input (including a user's personal identification code) may provide temporary access (i.e. replay the one-time passcode until the next value rollover) as well as possibly enabling adversaries to reliably predict future authentication values (given access to both the algorithm and any seed values used to generate appended temporary codes). (Citation: GCN RSA June 2011)

Other methods of MFA may be intercepted and used by an adversary to authenticate. It is common for one-time codes to be sent via out-of-band communications (email, SMS). If the device and/or

service is not secured, then it may be vulnerable to interception. Service providers can also be targeted: for example, an adversary may compromise an SMS messaging service in order to steal MFA codes sent to users' phones.(Citation: Okta Scatter Swine 2022)

Search Victim-Owned Websites - T1594

Adversaries may search websites owned by the victim for information that can be used during targeting. Victim-owned websites may contain a variety of details, including names of departments/divisions, physical locations, and data about key employees such as names, roles, and contact info (ex: [Email Addresses](https://attack.mitre.org/techniques/T1589/002)). These sites may also have details highlighting business operations and relationships.(Citation: Comparitech Leak)

Adversaries may search victim-owned websites to gather actionable information. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](https://attack.mitre.org/techniques/T1598) or [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596)), establishing operational resources (ex: [Establish Accounts](https://attack.mitre.org/techniques/T1585) or [Compromise Accounts](https://attack.mitre.org/techniques/T1586)), and/or initial access (ex: [Trusted Relationship](https://attack.mitre.org/techniques/T1199) or [Phishing](https://attack.mitre.org/techniques/T1566)).

In addition to manually browsing the website, adversaries may attempt to identify hidden directories or files that could contain additional sensitive information or vulnerable functionality. They may do this through automated activities such as [Wordlist Scanning](https://attack.mitre.org/techniques/T1595/003), as well as by leveraging files such as sitemap.xml and robots.txt.(Citation: Perez Sitemap XML 2023)(Citation: Register Robots TXT 2015)

/etc/passwd and /etc/shadow - T1003.008

Adversaries may attempt to dump the contents of <code>/etc/passwd</code> and <code>/etc/shadow</code> to enable offline password cracking. Most modern Linux operating systems use a combination of <code>/etc/passwd</code> and <code>/etc/shadow</code> to store user account information, including password hashes in <code>/etc/shadow</code>. By default, <code>/etc/shadow</code> is only readable by the root user.(Citation: Linux Password and Shadow File Formats)

Linux stores user information such as user ID, group ID, home directory path, and login shell in <code>/etc/passwd</code>. A "user" on the system may belong to a person or a service. All password hashes are stored in <code>/etc/shadow</code> - including entries for users with no passwords and users with locked or disabled accounts.(Citation: Linux Password and Shadow File Formats)

Adversaries may attempt to read or dump the <code>/etc/passwd</code> and <code>/etc/shadow</code> files on Linux systems via command line utilities such as the <code>cat</code> command.(Citation: Arctic Wolf) Additionally, the Linux utility <code>unshadow</code> can be used to combine the two files in a format suited for password cracking utilities such as John the Ripper - for example, via the command <code>/usr/bin/unshadow /etc/passwd /etc/shadow > /tmp/crack.password.db</code>(Citation: nixCraft - John the Ripper). Since the user information stored in <code>/etc/passwd</code> are linked to the password hashes in <code>/etc/shadow</code>, an adversary would need to have access to both.

The tag is: *misp-galaxy:mitre-attack-pattern="/etc/passwd and /etc/shadow - T1003.008"*

SMB/Windows Admin Shares - T1021.002

Adversaries may use [Valid Accounts](https://attack.mitre.org/techniques/T1078) to interact with a remote network share using Server Message Block (SMB). The adversary may then perform actions as the logged-on user.

SMB is a file, printer, and serial port sharing protocol for Windows machines on the same network or domain. Adversaries may use SMB to interact with file shares, allowing them to move laterally throughout a network. Linux and macOS implementations of SMB typically use Samba.

Windows systems have hidden network shares that are accessible only to administrators and provide the ability for remote file copy and other administrative functions. Example network shares include `C$`, `ADMIN$`, and `IPC$`. Adversaries may use this technique in conjunction with administrator-level [Valid Accounts](https://attack.mitre.org/techniques/T1078) to remotely access a networked system over SMB,(Citation: Wikipedia Server Message Block) to interact with systems using remote procedure calls (RPCs),(Citation: TechNet RPC) transfer files, and run transferred binaries through remote Execution. Example execution techniques that rely on authenticated sessions over SMB/RPC are [Scheduled Task/Job](https://attack.mitre.org/techniques/T1053), [Service Execution](https://attack.mitre.org/techniques/T1569/002), and [Windows Management Instrumentation](https://attack.mitre.org/techniques/T1047). Adversaries can also use NTLM hashes to access administrator shares on systems with [Pass the Hash](https://attack.mitre.org/techniques/T1550/002) and certain configuration and patch levels.(Citation: Microsoft Admin Shares)

Disguise Root/Jailbreak Indicators - T1630.003

An adversary could use knowledge of the techniques used by security software to evade detection.(Citation: Brodie)(Citation: Tan) For example, some mobile security products perform compromised device detection by searching for particular artifacts such as an installed "su" binary, but that check could be evaded by naming the binary something else. Similarly, polymorphic code techniques could be used to evade signature-based detection.(Citation: Rastogi)

Reduce Key Space - T1600.001

Adversaries may reduce the level of effort required to decrypt data transmitted over the network by reducing the cipher strength of encrypted communications.(Citation: Cisco Synful Knock Evolution)

Adversaries can weaken the encryption software on a compromised network device by reducing

the key size used by the software to convert plaintext to ciphertext (e.g., from hundreds or thousands of bytes to just a couple of bytes). As a result, adversaries dramatically reduce the amount of effort needed to decrypt the protected information without the key.

Adversaries may modify the key size used and other encryption parameters using specialized commands in a [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) introduced to the system through [Modify System Image](https://attack.mitre.org/techniques/T1601) to change the configuration of the device. (Citation: Cisco Blog Legacy Device Attacks)

The tag is: *misp-galaxy:mitre-attack-pattern="Reduce Key Space - T1600.001"*

Table 8251. Table References

Security Account Manager - T1003.002

Adversaries may attempt to extract credential material from the Security Account Manager (SAM) database either through in-memory techniques or through the Windows Registry where the SAM database is stored. The SAM is a database file that contains local accounts for the host, typically those found with the <code>net user</code> command. Enumerating the SAM database requires SYSTEM level access.

A number of tools can be used to retrieve the SAM file through in-memory techniques:

- pwdumpx.exe
- [gsecdump](https://attack.mitre.org/software/S0008)
- [Mimikatz](https://attack.mitre.org/software/S0002)
- secretsdump.py

Alternatively, the SAM can be extracted from the Registry with Reg:

- <code>reg save HKLM\sam sam</code>
- <code>reg save HKLM\system system</code>

Creddump7 can then be used to process the SAM database locally to retrieve hashes.(Citation: GitHub Creddump7)

Notes:

- RID 500 account is the local, built-in administrator.
- RID 501 is the guest account.
- User accounts start with a RID of 1,000+.

Disable Crypto Hardware - T1600.002

Adversaries disable a network device's dedicated hardware encryption, which may enable them to leverage weaknesses in software encryption in order to reduce the effort involved in collecting, manipulating, and exfiltrating transmitted data.

Many network devices such as routers, switches, and firewalls, perform encryption on network traffic to secure transmission across networks. Often, these devices are equipped with special, dedicated encryption hardware to greatly increase the speed of the encryption process as well as to prevent malicious tampering. When an adversary takes control of such a device, they may disable the dedicated hardware, for example, through use of [Modify System Image](https://attack.mitre.org/techniques/T1601), forcing the use of software to perform encryption on general processors. This is typically used in conjunction with attacks to weaken the strength of the cipher in software (e.g., [Reduce Key Space](https://attack.mitre.org/techniques/T1600/001)). (Citation: Cisco Blog Legacy Device Attacks)

The tag is: *misp-galaxy:mitre-attack-pattern="Disable Crypto Hardware - T1600.002"*

Cached Domain Credentials - T1003.005

Adversaries may attempt to access cached domain credentials used to allow authentication to occur in the event a domain controller is unavailable.(Citation: Microsoft - Cached Creds)

On Windows Vista and newer, the hash format is DCC2 (Domain Cached Credentials version 2) hash, also known as MS-Cache v2 hash.(Citation: PassLib mscache) The number of default cached credentials varies and can be altered per system. This hash does not allow pass-the-hash style attacks, and instead requires [Password Cracking](https://attack.mitre.org/techniques/T1110/002) to recover the plaintext password.(Citation: ired mscache)

On Linux systems, Active Directory credentials can be accessed through caches maintained by software like System Security Services Daemon (SSSD) or Quest Authentication Services (formerly VAS). Cached credential hashes are typically located at `/var/lib/sss/db/cache.[domain].ldb` for SSSD or `/var/opt/quest/vas/authcache/vas_auth.vdb` for Quest. Adversaries can use utilities, such as

`tdbdump`, on these database files to dump the cached hashes and use [Password Cracking](https://attack.mitre.org/techniques/T1110/002) to obtain the plaintext password.(Citation: Brining MimiKatz to Unix)

With SYSTEM or sudo access, the tools/utilities such as [Mimikatz](https://attack.mitre.org/software/S0002), [Reg](https://attack.mitre.org/software/S0075), and secretsdump.py for Windows or Linikatz for Linux can be used to extract the cached credentials.(Citation: Brining MimiKatz to Unix)

Note: Cached credentials for Windows Vista are derived using PBKDF2.(Citation: PassLib mscache)

The tag is: *misp-galaxy:mitre-attack-pattern="Cached Domain Credentials - T1003.005"*

Clear Command History - T1070.003

In addition to clearing system logs, an adversary may clear the command history of a compromised account to conceal the actions undertaken during an intrusion. Various command interpreters keep track of the commands users type in their terminal so that users can retrace what they've done.

On Linux and macOS, these command histories can be accessed in a few different ways. While logged in, this command history is tracked in a file pointed to by the environment variable <code>HISTFILE</code>. When a user logs off a system, this information is flushed to a file in the user's home directory called <code>~/.bash_history</code>. The benefit of this is that it allows users to go back to commands they've used before in different sessions. Adversaries may delete their commands from these logs by manually clearing the history (<code>history -c</code>) or deleting the bash history file <code>rm ~/.bash_history</code>.

Adversaries may also leverage a [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) on network devices to clear command history data (<code>clear logging</code> and/or <code>clear history</code>).(Citation: US-CERT-TA18-106A) On ESXi servers, command history may be manually removed from the `/var/log/shell.log` file.(Citation: Broadcom ESXi Shell Audit)

On Windows hosts, PowerShell has two different command history providers: the built-in history and the command history managed by the <code>PSReadLine</code> module. The built-in history only tracks the commands used in the current session. This command history is not available to

other sessions and is deleted when the session ends.

The <code>PSReadLine</code> command history tracks the commands used in all PowerShell sessions and writes them to a file (<code>$env:APPDATA\Microsoft\Windows\PowerShell\PSReadLine\ConsoleHost_history.txt</code> by default). This history file is available to all sessions and contains all past history since the file is not deleted when the session ends.(Citation: Microsoft PowerShell Command History)

Adversaries may run the PowerShell command <code>Clear-History</code> to flush the entire command history from a current PowerShell session. This, however, will not delete/flush the <code>ConsoleHost_history.txt</code> file. Adversaries may also delete the <code>ConsoleHost_history.txt</code> file or edit its contents to hide PowerShell commands they have run.(Citation: Sophos PowerShell command audit)(Citation: Sophos PowerShell Command History Forensics)

The tag is: *misp-galaxy:mitre-attack-pattern="Clear Command History - T1070.003"*

Clear Mailbox Data - T1070.008

Adversaries may modify mail and mail application data to remove evidence of their activity. Email applications allow users and other programs to export and delete mailbox data via command line tools or use of APIs. Mail application data can be emails, email metadata, or logs generated by the application or operating system, such as export requests.

Adversaries may manipulate emails and mailbox data to remove logs, artifacts, and metadata, such as evidence of [Phishing](Internal Spearphishing(https://attack.mitre.org/techniques/T1534), [Email Collection](https://attack.mitre.org/techniques/T1114), [Mail Protocols](https://attack.mitre.org/techniques/T1071/003) for command and control, or email-based exfiltration such as [Exfiltration Over Alternative Protocol](https://attack.mitre.org/techniques/T1048). For example, to remove evidence on Exchange servers adversaries have used the <code>ExchangePowerShell</code> [PowerShell](https://attack.mitre.org/techniques/T1059/001) module, including <code>Remove-MailboxExportRequest</code> to remove evidence of mailbox exports.(Citation: Volexity SolarWinds)(Citation: ExchangePowerShell Module) On Linux and macOS, adversaries may also delete emails through a command line utility called <code>mail</code> or use

[AppleScript](https://attack.mitre.org/techniques/T1059/002) to interact with APIs on macOS.(Citation: Cybereason Cobalt Kitty 2017)(Citation: mailx man page)

Adversaries may also remove emails and metadata/headers indicative of spam or suspicious activity (for example, through the use of organization-wide transport rules) to reduce the likelihood of malicious emails being detected by security products.(Citation: Microsoft OAuth Spam 2022)

Exfiltration Over Bluetooth - T1011.001

Adversaries may attempt to exfiltrate data over Bluetooth rather than the command and control channel. If the command and control network is a wired Internet connection, an adversary may opt to exfiltrate data using a Bluetooth communication channel.

Adversaries may choose to do this if they have sufficient access and proximity. Bluetooth connections might not be secured or defended as well as the primary Internet-connected channel because it is not routed through the same enterprise network.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration Over Bluetooth - T1011.001"*

Table 8257. Table References

Links

Dead Drop Resolver - T1102.001

Adversaries may use an existing, legitimate external Web service to host information that points to additional command and control (C2) infrastructure. Adversaries may post content, known as a dead drop resolver, on Web services with embedded (and often obfuscated/encoded) domains or IP addresses. Once infected, victims will reach out to and be redirected by these resolvers.

Popular websites and social media acting as a mechanism for C2 may give a significant amount of

cover due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

Use of a dead drop resolver may also protect back-end C2 infrastructure from discovery through malware binary analysis while also enabling operational resiliency (since this infrastructure may be dynamically changed).

The tag is: *misp-galaxy:mitre-attack-pattern="Dead Drop Resolver - T1102.001"*

Remote Desktop Protocol - T1021.001

Adversaries may use [Valid Accounts](https://attack.mitre.org/techniques/T1078) to log into a computer using the Remote Desktop Protocol (RDP). The adversary may then perform actions as the logged-on user.

Remote desktop is a common feature in operating systems. It allows a user to log into an interactive session with a system desktop graphical user interface on a remote system. Microsoft refers to its implementation of the Remote Desktop Protocol (RDP) as Remote Desktop Services (RDS).(Citation: TechNet Remote Desktop Services)

Adversaries may connect to a remote system over RDP/RDS to expand access if the service is enabled and allows access to accounts with known credentials. Adversaries will likely use Credential Access techniques to acquire credentials to use with RDP. Adversaries may also use RDP in conjunction with the [Accessibility Features](https://attack.mitre.org/techniques/T1546/008) or [Terminal Services DLL](https://attack.mitre.org/techniques/T1505/005) for Persistence.(Citation: Alperovitch Malware)

Internet Connection Discovery - T1016.001

Adversaries may check for Internet connectivity on compromised systems. This may be performed during automated discovery and can be accomplished in numerous ways such as using [Ping](https://attack.mitre.org/software/S0097), <code>tracert</code>, and GET requests to websites, or performing initial speed testing to confirm bandwidth.

Adversaries may use the results and responses from these requests to determine if the system is capable of communicating with their C2 servers before attempting to connect to them. The results may also be used to identify routes, redirectors, and proxy servers.

The tag is: *misp-galaxy:mitre-attack-pattern="Internet Connection Discovery - T1016.001"*

Table 8260. Table References

Patch System Image - T1601.001

Adversaries may modify the operating system of a network device to introduce new capabilities or weaken existing defenses.(Citation: Killing the myth of Cisco IOS rootkits) (Citation: Killing IOS diversity myth) (Citation: Cisco IOS Shellcode) (Citation: Cisco IOS Forensics Developments) (Citation: Juniper Netscreen of the Dead) Some network devices are built with a monolithic architecture, where the entire operating system and most of the functionality of the device is contained within a single file. Adversaries may change this file in storage, to be loaded in a future boot, or in memory during runtime.

To change the operating system in storage, the adversary will typically use the standard procedures available to device operators. This may involve downloading a new file via typical protocols used on network devices, such as TFTP, FTP, SCP, or a console connection. The original file may be overwritten, or a new file may be written alongside of it and the device reconfigured to boot to the compromised image.

To change the operating system in memory, the adversary typically can use one of two methods. In the first, the adversary would make use of native debug commands in the original, unaltered running operating system that allow them to directly modify the relevant memory addresses containing the running operating system. This method typically requires administrative level access to the device.

In the second method for changing the operating system in memory, the adversary would make use of the boot loader. The boot loader is the first piece of software that loads when the device starts that, in turn, will launch the operating system. Adversaries may use malicious code previously implanted in the boot loader, such as through the [ROMMONkit](https://attack.mitre.org/techniques/T1542/004) method, to directly manipulate running operating system code in memory. This malicious code in the bootloader provides the capability of direct memory manipulation to the adversary, allowing them to patch the live operating system during runtime.

By modifying the instructions stored in the system image file, adversaries may either weaken

existing defenses or provision new capabilities that the device did not have before. Examples of existing defenses that can be impeded include encryption, via [Weaken Encryption](https://attack.mitre.org/techniques/T1600), authentication, via [Network Device Authentication](https://attack.mitre.org/techniques/T1556/004), and perimeter defenses, via [Network Boundary Bridging](https://attack.mitre.org/techniques/T1599). Adding new capabilities for the adversary's purpose include [Keylogging](https://attack.mitre.org/techniques/T1056/001), [Multi-hop Proxy](https://attack.mitre.org/techniques/T1090/003), and [Port Knocking](https://attack.mitre.org/techniques/T1205/001).

Adversaries may also compromise existing commands in the operating system to produce false output to mislead defenders. When this method is used in conjunction with [Downgrade System Image](https://attack.mitre.org/techniques/T1601/002), one example of a compromised system command may include changing the output of the command that shows the version of the currently running operating system. By patching the operating system, the adversary can change this command to instead display the original, higher revision number that they replaced through the system downgrade.

When the operating system is patched in storage, this can be achieved in either the resident storage (typically a form of flash memory, which is non-volatile) or via [TFTP Boot](https://attack.mitre.org/techniques/T1542/005).

When the technique is performed on the running operating system in memory and not on the stored copy, this technique will not survive across reboots. However, live memory modification of the operating system can be combined with [ROMMONkit](https://attack.mitre.org/techniques/T1542/004) to achieve persistence.

The tag is: *misp-galaxy:mitre-attack-pattern="Patch System Image - T1601.001"*

Exfiltration over USB - T1052.001

Adversaries may attempt to exfiltrate data over a USB connected physical device. In certain circumstances, such as an air-gapped network compromise, exfiltration could occur via a USB device introduced by a user. The USB device could be used as the final exfiltration point or to hop

between otherwise disconnected systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration over USB - T1052.001"*

Table 8262. Table References

Links
https://attack.mitre.org/techniques/T1052/001

Downgrade System Image - T1601.002

Adversaries may install an older version of the operating system of a network device to weaken security. Older operating system versions on network devices often have weaker encryption ciphers and, in general, fewer/less updated defensive features. (Citation: Cisco Synful Knock Evolution)

On embedded devices, downgrading the version typically only requires replacing the operating system file in storage. With most embedded devices, this can be achieved by downloading a copy of the desired version of the operating system file and reconfiguring the device to boot from that file on next system restart. The adversary could then restart the device to implement the change immediately or they could wait until the next time the system restarts.

Downgrading the system image to an older versions may allow an adversary to evade defenses by enabling behaviors such as [Weaken Encryption](https://attack.mitre.org/techniques/T1600). Downgrading of a system image can be done on its own, or it can be used in conjunction with [Patch System Image](https://attack.mitre.org/techniques/T1601/001).

Windows Remote Management - T1021.006

Adversaries may use [Valid Accounts](https://attack.mitre.org/techniques/T1078) to interact with remote systems using Windows Remote Management (WinRM). The adversary may then perform actions as the logged-on user.

WinRM is the name of both a Windows service and a protocol that allows a user to interact with a remote system (e.g., run an executable, modify the Registry, modify services).(Citation: Microsoft WinRM) It may be called with the `winrm` command or by any number of programs such as PowerShell.(Citation: Jacobsen 2014) WinRM can be used as a method of remotely interacting with [Windows Management Instrumentation](https://attack.mitre.org/techniques/T1047).(Citation: MSDN WMI)

File Transfer Protocols - T1071.002

Adversaries may communicate using application layer protocols associated with transferring files to avoid detection/network filtering by blending in with existing traffic. Commands to the remote system, and often the results of those commands, will be embedded within the protocol traffic between the client and server.

Protocols such as SMB(Citation: US-CERT TA18-074A), FTP(Citation: ESET Machete July 2019), FTPS, and TFTP that transfer files may be very common in environments. Packets produced from these protocols may have many fields and headers in which data can be concealed. Data could also be concealed within the transferred files. An adversary may abuse these protocols to communicate with systems under their control within a victim network while also mimicking normal, expected traffic.

The tag is: *misp-galaxy:mitre-attack-pattern="File Transfer Protocols - T1071.002"*

Masquerade Account Name - T1036.010

Adversaries may match or approximate the names of legitimate accounts to make newly created ones appear benign. This will typically occur during [Create Account](https://attack.mitre.org/techniques/T1136), although accounts may also be renamed at a later date. This may also coincide with [Account Access Removal](https://attack.mitre.org/techniques/T1531) if the actor first deletes an account before re-creating one with the same name.(Citation: Huntress MOVEit 2023)

Often, adversaries will attempt to masquerade as service accounts, such as those associated with legitimate software, data backups, or container cluster management.(Citation: Elastic CUBA Ransomware 2022)(Citation: Aquasec Kubernetes Attack 2023) They may also give accounts generic,

trustworthy names, such as “admin”, “help”, or “root.”(Citation: Invictus IR Cloud Ransomware 2024) Sometimes adversaries may model account names off of those already existing in the system, as a follow-on behavior to [Account Discovery](https://attack.mitre.org/techniques/T1087).

Note that this is distinct from [Impersonation](https://attack.mitre.org/techniques/T1656), which describes impersonating specific trusted individuals or organizations, rather than user or service account names.

The tag is: *misp-galaxy:mitre-attack-pattern="Masquerade Account Name - T1036.010"*

Uninstall Malicious Application - T1630.001

Adversaries may include functionality in malware that uninstalls the malicious application from the device. This can be achieved by:

- Abusing device owner permissions to perform silent uninstallation using device owner API calls.
- Abusing root permissions to delete files from the filesystem.
- Abusing the accessibility service. This requires sending an intent to the system to request uninstallation, and then abusing the accessibility service to click the proper places on the screen to confirm uninstallation.

The tag is: *misp-galaxy:mitre-attack-pattern="Uninstall Malicious Application - T1630.001"*

Table 8267. Table References

Links

https://pages.nist.gov/mobile-threat-catalogue/application-threats/APP-43.html

Invalid Code Signature - T1036.001

Adversaries may attempt to mimic features of valid code signatures to increase the chance of deceiving a user, analyst, or tool. Code signing provides a level of authenticity on a binary from the developer and a guarantee that the binary has not been tampered with. Adversaries can copy the metadata and signature information from a signed program, then use it as a template for an unsigned program. Files with invalid code signatures will fail digital signature validation checks,

but they may appear more legitimate to users and security tools may improperly handle these files.(Citation: Threatexpress MetaTwin 2017)

Unlike [Code Signing](https://attack.mitre.org/techniques/T1553/002), this activity will not result in a valid signature.

The tag is: *misp-galaxy:mitre-attack-pattern="Invalid Code Signature - T1036.001"*

Table 8268. Table References

Local Data Staging - T1074.001

Adversaries may stage collected data in a central location or directory on the local system prior to Exfiltration. Data may be kept in separate files or combined into one file through techniques such as [Archive Collected Data](https://attack.mitre.org/techniques/T1560). Interactive command shells may be used, and common functionality within [cmd](https://attack.mitre.org/software/S0106) and bash may be used to copy data into a staging location.

Adversaries may also stage collected data in various available formats/locations of a system, including local storage databases/repositories or the Windows Registry.(Citation: Prevailion DarkWatchman 2021)

The tag is: *misp-galaxy:mitre-attack-pattern="Local Data Staging - T1074.001"*

Table 8269. Table References

Links

Application Access Token - T1550.001

Adversaries may use stolen application access tokens to bypass the typical authentication process and access restricted accounts, information, or services on remote systems. These tokens are typically stolen from users or services and used in lieu of login credentials.

Application access tokens are used to make authorized API requests on behalf of a user or service and are commonly used to access resources in cloud, container-based applications, and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019)

OAuth is one commonly implemented framework that issues tokens to users for access to systems.

These frameworks are used collaboratively to verify the user and determine what actions the user is allowed to perform. Once identity is established, the token allows actions to be authorized, without passing the actual credentials of the user. Therefore, compromise of the token can grant the adversary access to resources of other sites through a malicious application.(Citation: okta)

For example, with a cloud-based email service, once an OAuth access token is granted to a malicious application, it can potentially gain long-term access to features of the user account if a "refresh" token enabling background access is awarded.(Citation: Microsoft Identity Platform Access 2019) With an OAuth access token an adversary can use the user-granted REST API to perform functions such as email searching and contact enumeration.(Citation: Staaldraad Phishing with OAuth 2017)

Compromised access tokens may be used as an initial step in compromising other services. For example, if a token grants access to a victim's primary email, the adversary may be able to extend access to all other services which the target subscribes by triggering forgotten password routines. In AWS and GCP environments, adversaries can trigger a request for a short-lived access token with the privileges of another user account.(Citation: Google Cloud Service Account Credentials)(Citation: AWS Temporary Security Credentials) The adversary can then use this token to request data or perform actions the original account could not. If permissions for this feature are misconfigured – for example, by allowing all users to request a token for a particular account - an adversary may be able to gain initial access to a Cloud Account or escalate their privileges.(Citation: Rhino Security Labs Enumerating AWS Roles)

Direct API access through a token negates the effectiveness of a second authentication factor and may be immune to intuitive countermeasures like changing passwords. For example, in AWS environments, an adversary who compromises a user's AWS API credentials may be able to use the `sts:GetFederationToken` API call to create a federated user session, which will have the same permissions as the original user but may persist even if the original user credentials are deactivated.(Citation: Crowdstrike AWS User Federation Persistence) Additionally, access abuse over an API channel can be difficult to detect even from the service provider end, as the access can still align well with a legitimate workflow.

The tag is: *misp-galaxy:mitre-attack-pattern="Application Access Token - T1550.001"*

SQL Stored Procedures - T1505.001

Adversaries may abuse SQL stored procedures to establish persistent access to systems. SQL Stored Procedures are code that can be saved and reused so that database users do not waste time rewriting frequently used SQL queries. Stored procedures can be invoked via SQL statements to the database using the procedure name or via defined events (e.g. when a SQL server application is started/restarted).

Adversaries may craft malicious stored procedures that can provide a persistence mechanism in SQL database servers.(Citation: NetSPI Startup Stored Procedures)(Citation: Kaspersky MSSQL Aug 2019) To execute operating system commands through SQL syntax the adversary may have to enable additional functionality, such as xp_cmdshell for MSSQL Server.(Citation: NetSPI Startup Stored Procedures)(Citation: Kaspersky MSSQL Aug 2019)(Citation: Microsoft xp_cmdshell 2017)

Microsoft SQL Server can enable common language runtime (CLR) integration. With CLR integration enabled, application developers can write stored procedures using any .NET framework language (e.g. VB .NET, C#, etc.).(Citation: Microsoft CLR Integration 2017) Adversaries may craft or modify CLR assemblies that are linked to stored procedures since these CLR assemblies can be made to execute arbitrary commands.(Citation: NetSPI SQL Server CLR)

The tag is: *misp-galaxy:mitre-attack-pattern="SQL Stored Procedures - T1505.001"*

Archive via Utility - T1560.001

Adversaries may use utilities to compress and/or encrypt collected data prior to exfiltration. Many utilities include functionalities to compress, encrypt, or otherwise package data into a format that is easier/more secure to transport.

Adversaries may abuse various utilities to compress or encrypt data before exfiltration. Some third

party utilities may be preinstalled, such as <code>tar</code> on Linux and macOS or <code>zip</code> on Windows systems.

On Windows, <code>diantz</code> or <code> makecab</code> may be used to package collected files into a cabinet (.cab) file. <code>diantz</code> may also be used to download and compress files from remote locations (i.e. [Remote Data Staging](https://attack.mitre.org/techniques/T1074/002)).(Citation: diantz.exe_lolbas) <code>xcopy</code> on Windows can copy files and directories with a variety of options. Additionally, adversaries may use [certutil](https://attack.mitre.org/software/S0160) to Base64 encode collected data before exfiltration.

Adversaries may use also third party utilities, such as 7-Zip, WinRAR, and WinZip, to perform similar activities.(Citation: 7zip Homepage)(Citation: WinRAR Homepage)(Citation: WinZip Homepage)

The tag is: *misp-galaxy:mitre-attack-pattern="Archive via Utility - T1560.001"*

Additional Cloud Credentials - T1098.001

Adversaries may add adversary-controlled credentials to a cloud account to maintain persistent access to victim accounts and instances within the environment.

For example, adversaries may add credentials for Service Principals and Applications in addition to existing legitimate credentials in Azure / Entra ID.(Citation: Microsoft SolarWinds Customer Guidance)(Citation: Blue Cloud of Death)(Citation: Blue Cloud of Death Video) These credentials include both x509 keys and passwords.(Citation: Microsoft SolarWinds Customer Guidance) With sufficient permissions, there are a variety of ways to add credentials including the Azure Portal, Azure command line interface, and Azure or Az PowerShell modules.(Citation: Demystifying Azure AD Service Principals)

In infrastructure-as-a-service (IaaS) environments, after gaining access through [Cloud Accounts](https://attack.mitre.org/techniques/T1078/004), adversaries may generate or import their own SSH keys using either the <code>CreateKeyPair</code> or <code>ImportKeyPair</code> API in AWS or the <code>gcloud compute os-login ssh-keys add</code> command in GCP.(Citation: GCP SSH Key Add) This allows persistent access to instances within the cloud environment without further usage of the compromised cloud accounts.(Citation: Expel IO Evil in AWS)(Citation: Expel Behind the Scenes)

Adversaries may also use the <code>CreateAccessKey</code> API in AWS or the <code>gcloud iam service-accounts keys create</code> command in GCP to add access keys to an account. Alternatively, they may use the <code>CreateLoginProfile</code> API in AWS to add a password that can be used to log into the AWS Management Console for [Cloud Service Dashboard](https://attack.mitre.org/techniques/T1538).(Citation: Permiso Scattered Spider 2023)(Citation: Lacework AI Resource Hijacking 2024) If the target account has different permissions from the requesting account, the adversary may also be able to escalate their privileges in the environment (i.e. [Cloud Accounts](https://attack.mitre.org/techniques/T1078/004)).(Citation: Rhino Security Labs AWS Privilege Escalation)(Citation: Sysdig ScarletEel 2.0) For example, in Entra ID environments, an adversary with the Application Administrator role can add a new set of credentials to their application's service principal. In doing so the adversary would be able to access the service principal's roles and permissions, which may be different from those of the Application Administrator.(Citation: SpecterOps Azure Privilege Escalation)

In AWS environments, adversaries with the appropriate permissions may also use the `sts:GetFederationToken` API call to create a temporary set of credentials to [Forge Web Credentials](https://attack.mitre.org/techniques/T1606) tied to the permissions of the original user account. These temporary credentials may remain valid for the duration of their lifetime even if the original account's API credentials are deactivated. (Citation: Crowdstrike AWS User Federation Persistence)

In Entra ID environments with the app password feature enabled, adversaries may be able to add an app password to a user account.(Citation: Mandiant APT42 Operations 2024) As app passwords are intended to be used with legacy devices that do not support multi-factor authentication (MFA), adding an app password can allow an adversary to bypass MFA requirements. Additionally, app passwords may remain valid even if the user's primary password is reset.(Citation: Microsoft Entra ID App Passwords)

Compile After Delivery - T1027.004

Adversaries may attempt to make payloads difficult to discover and analyze by delivering files to victims as uncompiled code. Text-based source code files may subvert analysis and scrutiny from protections targeting executables/binaries. These payloads will need to be compiled before execution; typically via native utilities such as ilasm.exe(Citation: ATTACK IQ), csc.exe, or GCC/MinGW.(Citation: ClearSky MuddyWater Nov 2018)

Source code payloads may also be encrypted, encoded, and/or embedded within other files, such as those delivered as a [Phishing](https://attack.mitre.org/techniques/T1566). Payloads may also be delivered in formats unrecognizable and inherently benign to the native OS (ex: EXEs on macOS/Linux) before later being (re)compiled into a proper executable binary with a bundled

compiler and execution framework.(Citation: TrendMicro WindowsAppMac)

Remote Data Staging - T1074.002

Adversaries may stage data collected from multiple systems in a central location or directory on one system prior to Exfiltration. Data may be kept in separate files or combined into one file through techniques such as [Archive Collected Data](https://attack.mitre.org/techniques/T1560). Interactive command shells may be used, and common functionality within [cmd](https://attack.mitre.org/software/S0106) and bash may be used to copy data into a staging location.

In cloud environments, adversaries may stage data within a particular instance or virtual machine before exfiltration. An adversary may [Create Cloud Instance](https://attack.mitre.org/techniques/T1578/002) and stage data in that instance.(Citation: Mandiant M-Trends 2020)

By staging data on one system prior to Exfiltration, adversaries can minimize the number of connections made to their C2 server and better evade detection.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote Data Staging - T1074.002"*

Portable Executable Injection - T1055.002

Adversaries may inject portable executables (PE) into processes in order to evade process-based defenses as well as possibly elevate privileges. PE injection is a method of executing arbitrary code in the address space of a separate live process.

PE injection is commonly performed by copying code (perhaps without a file on disk) into the virtual address space of the target process before invoking it via a new thread. The write can be performed with native Windows API calls such as <code>VirtualAllocEx</code> and

<code>WriteProcessMemory</code>, then invoked with <code>CreateRemoteThread</code> or additional code (ex: shellcode). The displacement of the injected code does introduce the additional requirement for functionality to remap memory references. (Citation: Elastic Process Injection July 2017)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via PE injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Portable Executable Injection - T1055.002"*

Pass the Hash - T1550.002

Adversaries may "pass the hash" using stolen password hashes to move laterally within an environment, bypassing normal system access controls. Pass the hash (PtH) is a method of authenticating as a user without having access to the user's cleartext password. This method bypasses standard authentication steps that require a cleartext password, moving directly into the portion of the authentication that uses the password hash.

When performing PtH, valid password hashes for the account being used are captured using a [Credential Access](https://attack.mitre.org/tactics/TA0006) technique. Captured hashes are used with PtH to authenticate as that user. Once authenticated, PtH may be used to perform actions on local or remote systems.

Adversaries may also use stolen password hashes to "overpass the hash." Similar to PtH, this involves using a password hash to authenticate as a user but also uses the password hash to create a valid Kerberos ticket. This ticket can then be used to perform [Pass the Ticket](https://attack.mitre.org/techniques/T1550/003) attacks.(Citation: Stealthbits Overpass-the-Hash)

The tag is: *misp-galaxy:mitre-attack-pattern="Pass the Hash - T1550.002"*

Table 8278. Table References

Archive via Library - T1560.002

An adversary may compress or encrypt data that is collected prior to exfiltration using 3rd party

libraries. Many libraries exist that can archive data, including [Python](https://attack.mitre.org/techniques/T1059/006) rarfile (Citation: PyPI RAR), libzip (Citation: libzip), and zlib (Citation: Zlib Github). Most libraries include functionality to encrypt and/or compress data.

Some archival libraries are preinstalled on systems, such as bzip2 on macOS and Linux, and zip on Windows. Note that the libraries are different from the utilities. The libraries can be linked against when compiling, while the utilities require spawning a subshell, or a similar execution mechanism.

The tag is: *misp-galaxy:mitre-attack-pattern="Archive via Library - T1560.002"*

GUI Input Capture - T1056.002

Adversaries may mimic common operating system GUI components to prompt users for credentials with a seemingly legitimate prompt. When programs are executed that need additional privileges than are present in the current user context, it is common for the operating system to prompt the user for proper credentials to authorize the elevated privileges for the task (ex: [Bypass User Account Control](https://attack.mitre.org/techniques/T1548/002)).

Adversaries may mimic this functionality to prompt users for credentials with a seemingly legitimate prompt for a number of reasons that mimic normal usage, such as a fake installer requiring additional access or a fake malware removal suite.(Citation: OSX Malware Exploits MacKeeper) This type of prompt can be used to collect credentials via various languages such as [AppleScript](https://attack.mitre.org/techniques/T1059/002)(Citation: LogRhythm Do You Trust Oct 2014)(Citation: OSX Keydnap malware)(Citation: Spoofing credential dialogs) and [PowerShell](https://attack.mitre.org/techniques/T1059/001).(Citation: LogRhythm Do You Trust Oct 2014)(Citation: Enigma Phishing for Credentials Jan 2015)(Citation: Spoofing credential dialogs) On Linux systems adversaries may launch dialog boxes prompting users for credentials from malicious shell scripts or the command line (i.e. [Unix Shell](https://attack.mitre.org/techniques/T1059/004)).(Citation: Spoofing credential dialogs)

Adversaries may also mimic common software authentication requests, such as those from browsers or email clients. This may also be paired with user activity monitoring (i.e., [Browser Information Discovery](https://attack.mitre.org/techniques/T1217) and/or [Application Window Discovery](https://attack.mitre.org/techniques/T1010)) to spoof prompts when users are naturally accessing sensitive sites/data.

Dynamic API Resolution - T1027.007

Adversaries may obfuscate then dynamically resolve API functions called by their malware in order to conceal malicious functionalities and impair defensive analysis. Malware commonly uses various [Native API](https://attack.mitre.org/techniques/T1106) functions provided by the OS to perform various tasks such as those involving processes, files, and other system artifacts.

API functions called by malware may leave static artifacts such as strings in payload files. Defensive analysts may also uncover which functions a binary file may execute via an import address table (IAT) or other structures that help dynamically link calling code to the shared modules that provide functions.(Citation: Huntress API Hash)(Citation: IRED API Hashing)

To avoid static or other defensive analysis, adversaries may use dynamic API resolution to conceal malware characteristics and functionalities. Similar to [Software Packing](https://attack.mitre.org/techniques/T1027/002), dynamic API resolution may change file signatures and obfuscate malicious API function calls until they are resolved and invoked during runtime.

Various methods may be used to obfuscate malware calls to API functions. For example, hashes of function names are commonly stored in malware in lieu of literal strings. Malware can use these hashes (or other identifiers) to manually reproduce the linking and loading process using functions such as `GetProcAddress()` and `LoadLibrary()`. These hashes/identifiers can also be further obfuscated using encryption or other string manipulation tricks (requiring various forms of [Deobfuscate/Decode Files or Information](https://attack.mitre.org/techniques/T1140) during execution).(Citation: BlackHat API Packers)(Citation: Drakonia HInvoke)(Citation: Huntress API Hash)

The tag is: *misp-galaxy:mitre-attack-pattern="Dynamic API Resolution - T1027.007"*

Rename Legitimate Utilities - T1036.003

Adversaries may rename legitimate / system utilities to try to evade security mechanisms concerning the usage of those utilities. Security monitoring and control mechanisms may be in place for legitimate utilities adversaries are capable of abusing, including both built-in binaries and tools such as PSExec, AutoHotKey, and IronPython.(Citation: LOLBAS Main Site)(Citation: Huntress Python Malware 2025)(Citation: The DFIR Report AutoHotKey 2023)(Citation: Splunk Detect Renamed PSExec) It may be possible to bypass those security mechanisms by renaming the utility prior to utilization (ex: rename <code>rundll32.exe</code>).(Citation: Elastic Masquerade Ball) An alternative case occurs when a legitimate utility is copied or moved to a different directory and renamed to avoid detections based on these utilities executing from non-standard paths.(Citation: F-Secure CozyDuke)

The tag is: *misp-galaxy:mitre-attack-pattern="Rename Legitimate Utilities - T1036.003"*

Network Logon Script - T1037.003

Adversaries may use network logon scripts automatically executed at logon initialization to establish persistence. Network logon scripts can be assigned using Active Directory or Group Policy Objects.(Citation: Petri Logon Script AD) These logon scripts run with the privileges of the user they are assigned to. Depending on the systems within the network, initializing one of these scripts could apply to more than one or potentially all systems.

Adversaries may use these scripts to maintain persistence on a network. Depending on the access configuration of the logon scripts, either local credentials or an administrator account may be necessary.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Logon Script - T1037.003"*

Table 8283. Table References

Links
https://attack.mitre.org/techniques/T1037/003
https://www.petri.com/setting-up-logon-script-through-active-directory-users-computers-windows-server-2008

Thread Execution Hijacking - T1055.003

Adversaries may inject malicious code into hijacked processes in order to evade process-based defenses as well as possibly elevate privileges. Thread Execution Hijacking is a method of executing arbitrary code in the address space of a separate live process.

Thread Execution Hijacking is commonly performed by suspending an existing process then unmapping/hollowing its memory, which can then be replaced with malicious code or the path to a DLL. A handle to an existing victim process is first created with native Windows API calls such as <code>OpenThread</code>. At this point the process can be suspended then written to, realigned to the injected code, and resumed via <code>SuspendThread </code>, <code>VirtualAllocEx</code>, <code>WriteProcessMemory</code>, <code>SetThreadContext</code>, then <code>ResumeThread</code> respectively.(Citation: Elastic Process Injection July 2017)

This is very similar to [Process Hollowing](https://attack.mitre.org/techniques/T1055/012) but targets an existing process rather than creating a process in a suspended state.

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via Thread Execution Hijacking may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Thread Execution Hijacking - T1055.003"*

Pass the Ticket - T1550.003

Adversaries may "pass the ticket" using stolen Kerberos tickets to move laterally within an environment, bypassing normal system access controls. Pass the ticket (PtT) is a method of authenticating to a system using Kerberos tickets without having access to an account's password. Kerberos authentication can be used as the first step to lateral movement to a remote system.

When preforming PtT, valid Kerberos tickets for [Valid Accounts](https://attack.mitre.org/techniques/T1078) are captured by [OS Credential Dumping](https://attack.mitre.org/techniques/T1003). A user's service tickets or ticket granting ticket (TGT) may be obtained, depending on the

level of access. A service ticket allows for access to a particular resource, whereas a TGT can be used to request service tickets from the Ticket Granting Service (TGS) to access any resource the user has privileges to access.(Citation: ADSecurity AD Kerberos Attacks)(Citation: GentilKiwi Pass the Ticket)

A [Silver Ticket](https://attack.mitre.org/techniques/T1558/002) can be obtained for services that use Kerberos as an authentication mechanism and are used to generate tickets to access that particular resource and the system that hosts the resource (e.g., SharePoint).(Citation: ADSecurity AD Kerberos Attacks)

A [Golden Ticket](https://attack.mitre.org/techniques/T1558/001) can be obtained for the domain using the Key Distribution Service account KRBTGT account NTLM hash, which enables generation of TGTs for any account in Active Directory.(Citation: Campbell 2014)

Adversaries may also create a valid Kerberos ticket using other user information, such as stolen password hashes or AES keys. For example, "overpassing the hash" involves using a NTLM password hash to authenticate as a user (i.e. [Pass the Hash](https://attack.mitre.org/techniques/T1550/002)) while also using the password hash to create a valid Kerberos ticket.(Citation: Stealthbits Overpass-the-Hash)

The tag is: *misp-galaxy:mitre-attack-pattern="Pass the Ticket - T1550.003"*

Container Orchestration Job - T1053.007

Adversaries may abuse task scheduling functionality provided by container orchestration tools such as Kubernetes to schedule deployment of containers configured to execute malicious code. Container orchestration jobs run these automated tasks at a specific date and time, similar to cron jobs on a Linux system. Deployments of this type can also be configured to maintain a quantity of containers over time, automating the process of maintaining persistence within a cluster.

In Kubernetes, a CronJob may be used to schedule a Job that runs one or more containers to perform specific tasks.(Citation: Kubernetes Jobs)(Citation: Kubernetes CronJob) An adversary therefore may utilize a CronJob to schedule deployment of a Job that executes malicious code in various nodes within a cluster.(Citation: Threat Matrix for Kubernetes)

The tag is: *misp-galaxy:mitre-attack-pattern="Container Orchestration Job - T1053.007"*

Windows Command Shell - T1059.003

Adversaries may abuse the Windows command shell for execution. The Windows command shell ([cmd](https://attack.mitre.org/software/S0106)) is the primary command prompt on Windows systems. The Windows command prompt can be used to control almost any aspect of a system, with various permission levels required for different subsets of commands. The command prompt can be invoked remotely via [Remote Services](https://attack.mitre.org/techniques/T1021) such as [SSH](https://attack.mitre.org/techniques/T1021/004).(Citation: SSH in Windows)

Batch files (ex: .bat or .cmd) also provide the shell with a list of sequential commands to run, as well as normal scripting operations such as conditionals and loops. Common uses of batch files include long or repetitive tasks, or the need to run the same set of commands on multiple systems.

Adversaries may leverage [cmd](https://attack.mitre.org/software/S0106) to execute various commands and payloads. Common uses include [cmd](https://attack.mitre.org/software/S0106) to

execute a single command, or abusing [cmd](https://attack.mitre.org/software/S0106) interactively with input and output forwarded over a command and control channel.

Network Trust Dependencies - T1590.003

Adversaries may gather information about the victim's network trust dependencies that can be used during targeting. Information about network trusts may include a variety of details, including second or third-party organizations/domains (ex: managed service providers, contractors, etc.) that have connected (and potentially elevated) network access.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](https://attack.mitre.org/techniques/T1598). Information about network trusts may also be exposed to adversaries via online or other accessible data sets (ex: [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596)).(Citation: Pentesting AD Forests) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](https://attack.mitre.org/techniques/T1595) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Acquire Infrastructure](https://attack.mitre.org/techniques/T1583) or [Compromise Infrastructure](https://attack.mitre.org/techniques/T1584)), and/or initial access (ex: [Trusted Relationship](https://attack.mitre.org/techniques/T1199)).

The tag is: *misp-galaxy:mitre-attack-pattern="Network Trust Dependencies - T1590.003"*

Space after Filename - T1036.006

Adversaries can hide a program's true filetype by changing the extension of a file. With certain file types (specifically this does not work with .app extensions), appending a space to the end of a filename will change how the file is processed by the operating system.

For example, if there is a Mach-O executable file called <code>evil.bin</code>, when it is double clicked by a user, it will launch Terminal.app and execute. If this file is renamed to <code>evil.txt</code>, then when double clicked by a user, it will launch with the default text editing application (not executing the binary). However, if the file is renamed to <code>evil.txt </code> (note the space at the end), then when double clicked by a user, the true file type is

determined by the OS and handled appropriately and the binary will be executed (Citation: Mac Backdoors are back).

Adversaries can use this feature to trick users into double clicking benign-looking files of any format and ultimately executing something malicious.

The tag is: *misp-galaxy:mitre-attack-pattern="Space after Filename - T1036.006"*

Table 8290. Table References

Links
https://arstechnica.com/security/2016/07/after-hiatus-in-the-wild-mac-backdoors-are-suddenly-back/
https://attack.mitre.org/techniques/T1036/006

Double File Extension - T1036.007

Adversaries may abuse a double extension in the filename as a means of masquerading the true file type. A file name may include a secondary file type extension that may cause only the first extension to be displayed (ex: <code>File.txt.exe</code> may render in some views as just <code>File.txt</code>). However, the second extension is the true file type that determines how the file is opened and executed. The real file extension may be hidden by the operating system in the file browser (ex: explorer.exe), as well as in any software configured using or similar to the system's policies.(Citation: PCMag DoubleExtension)(Citation: SOCPrime DoubleExtension)

Adversaries may abuse double extensions to attempt to conceal dangerous file types of payloads. A very common usage involves tricking a user into opening what they think is a benign file type but is actually executable code. Such files often pose as email attachments and allow an adversary to gain [Initial Access](https://attack.mitre.org/tactics/TA0001) into a user's system via [Spearphishing Attachment](https://attack.mitre.org/techniques/T1566/001) then [User Execution](https://attack.mitre.org/techniques/T1204). For example, an executable file attachment named <code>Evil.txt.exe</code> may display as <code>Evil.txt</code> to a user. The user may then view it as a benign text file and open it, inadvertently executing the hidden malware.(Citation: SOCPrime DoubleExtension)

Common file types, such as text files (.txt, .doc, etc.) and image files (.jpg, .gif, etc.) are typically used as the first extension to appear benign. Executable extensions commonly regarded as dangerous, such as .exe, .lnk, .hta, and .scr, often appear as the second extension and true file type.

The tag is: *misp-galaxy:mitre-attack-pattern="Double File Extension - T1036.007"*

Install Digital Certificate - T1608.003

Adversaries may install SSL/TLS certificates that can be used during targeting. SSL/TLS certificates are files that can be installed on servers to enable secure communications between systems. Digital certificates include information about the key, information about its owner's identity, and the digital signature of an entity that has verified the certificate's contents are correct. If the signature is valid, and the person examining the certificate trusts the signer, then they know they can use that key to communicate securely with its owner. Certificates can be uploaded to a server, then the server can be configured to use the certificate to enable encrypted communication with it.(Citation: DigiCert Install SSL Cert)

Adversaries may install SSL/TLS certificates that can be used to further their operations, such as encrypting C2 traffic (ex: [Asymmetric Cryptography](https://attack.mitre.org/techniques/T1573/002) with [Web Protocols](https://attack.mitre.org/techniques/T1071/001)) or lending credibility to a credential harvesting site. Installation of digital certificates may take place for a number of server types, including web servers and email servers.

Adversaries can obtain digital certificates (see [Digital Certificates](https://attack.mitre.org/techniques/T1588/004)) or create self-signed certificates (see [Digital Certificates](https://attack.mitre.org/techniques/T1587/003)). Digital certificates can then be installed on adversary controlled infrastructure that may have been acquired ([Acquire Infrastructure](https://attack.mitre.org/techniques/T1583)) or previously compromised ([Compromise Infrastructure](https://attack.mitre.org/techniques/T1584)).

Masquerade File Type - T1036.008

Adversaries may masquerade malicious payloads as legitimate files through changes to the payload's formatting, including the file's signature, extension, icon, and contents. Various file types have a typical standard format, including how they are encoded and organized. For example, a file's signature (also known as header or magic bytes) is the beginning bytes of a file and is often used to identify the file's type. For example, the header of a JPEG file, is <code> 0xFF 0xD8</code> and the file extension is either `.JPE`, `.JPEG` or `.JPG`.

Adversaries may edit the header's hex code and/or the file extension of a malicious payload in order to bypass file validation checks and/or input sanitization. This behavior is commonly used

when payload files are transferred (e.g., [Ingress Tool Transfer](https://attack.mitre.org/techniques/T1105)) and stored (e.g., [Upload Malware](https://attack.mitre.org/techniques/T1608/001)) so that adversaries may move their malware without triggering detections.

Common non-executable file types and extensions, such as text files (`.txt`) and image files (`.jpg`, `.gif`, etc.) may be typically treated as benign. Based on this, adversaries may use a file extension to disguise malware, such as naming a PHP backdoor code with a file name of <code>test.gif</code>. A user may not know that a file is malicious due to the benign appearance and file extension.

Polyglot files, which are files that have multiple different file types and that function differently based on the application that will execute them, may also be used to disguise malicious malware and capabilities.(Citation: polygot_icedID)

Break Process Trees - T1036.009

An adversary may attempt to evade process tree-based analysis by modifying executed malware's parent process ID (PPID). If endpoint protection software leverages the "parent-child" relationship for detection, breaking this relationship could result in the adversary's behavior not being associated with previous process tree activity. On Unix-based systems breaking this process tree is common practice for administrators to execute software using scripts and programs.(Citation: 3OHA double-fork 2022)

On Linux systems, adversaries may execute a series of [Native API](https://attack.mitre.org/techniques/T1106) calls to alter malware's process tree. For example, adversaries can execute their payload without any arguments, call the `fork()` API call twice, then have the parent process exit. This creates a grandchild process with no parent process that is immediately adopted by the `init` system process (PID 1), which successfully disconnects the execution of the adversary's payload from its previous process tree.

Another example is using the "daemon" syscall to detach from the current parent process and run in the background.(Citation: Sandfly BPFDoor 2022)(Citation: Microsoft XorDdos Linux Stealth 2022)

The tag is: *misp-galaxy:mitre-attack-pattern="Break Process Trees - T1036.009"*

Additional Cloud Roles - T1098.003

An adversary may add additional roles or permissions to an adversary-controlled cloud account to maintain persistent access to a tenant. For example, adversaries may update IAM policies in cloud-based environments or add a new global administrator in Office 365 environments.(Citation: AWS IAM Policies and Permissions)(Citation: Google Cloud IAM Policies)(Citation: Microsoft Support O365 Add Another Admin, October 2019)(Citation: Microsoft O365 Admin Roles) With sufficient permissions, a compromised account can gain almost unlimited access to data and settings (including the ability to reset the passwords of other admins).(Citation: Expel AWS Attacker) (Citation: Microsoft O365 Admin Roles)

This account modification may immediately follow [Create Account](https://attack.mitre.org/techniques/T1136) or other malicious account activity. Adversaries may also modify existing [Valid Accounts](https://attack.mitre.org/techniques/T1078) that they have compromised. This could lead to privilege escalation, particularly if the roles added allow for lateral movement to additional accounts.

For example, in AWS environments, an adversary with appropriate permissions may be able to use the <code>CreatePolicyVersion</code> API to define a new version of an IAM policy or the <code>AttachUserPolicy</code> API to attach an IAM policy with additional or distinct permissions to a compromised user account.(Citation: Rhino Security Labs AWS Privilege Escalation)

In some cases, adversaries may add roles to adversary-controlled accounts outside the victim cloud tenant. This allows these external accounts to perform actions inside the victim tenant without requiring the adversary to [Create Account](https://attack.mitre.org/techniques/T1136) or modify a victim-owned account.(Citation: Invictus IR DangerDev 2024)

Asynchronous Procedure Call - T1055.004

Adversaries may inject malicious code into processes via the asynchronous procedure call (APC) queue in order to evade process-based defenses as well as possibly elevate privileges. APC injection is a method of executing arbitrary code in the address space of a separate live process.

APC injection is commonly performed by attaching malicious code to the APC Queue (Citation: Microsoft APC) of a process's thread. Queued APC functions are executed when the thread enters an alterable state.(Citation: Microsoft APC) A handle to an existing victim process is first created with native Windows API calls such as <code>OpenThread</code>. At this point <code>QueueUserAPC</code> can be used to invoke a function (such as <code>LoadLibrayA</code> pointing to a malicious DLL).

A variation of APC injection, dubbed "Early Bird injection", involves creating a suspended process in which malicious code can be written and executed before the process' entry point (and potentially subsequent anti-malware hooks) via an APC. (Citation: CyberBit Early Bird Apr 2018) AtomBombing (Citation: ENSIL AtomBombing Oct 2016) is another variation that utilizes APCs to invoke malicious code previously written to the global atom table.(Citation: Microsoft Atom Table)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via APC injection may also evade detection from security products since the execution is masked under a legitimate process.

Web Session Cookie - T1550.004

Adversaries can use stolen session cookies to authenticate to web applications and services. This technique bypasses some multi-factor authentication protocols since the session is already authenticated.(Citation: Pass The Cookie)

Authentication cookies are commonly used in web applications, including cloud-based services, after a user has authenticated to the service so credentials are not passed and re-authentication does not need to occur as frequently. Cookies are often valid for an extended period of time, even if the web application is not actively used. After the cookie is obtained through [Steal Web Session

Cookie](https://attack.mitre.org/techniques/T1539) or [Web Cookies](https://attack.mitre.org/techniques/T1606/001), the adversary may then import the cookie into a browser they control and is then able to use the site or application as the user for as long as the session cookie is active. Once logged into the site, an adversary can access sensitive information, read email, or perform actions that the victim account has permissions to perform.

There have been examples of malware targeting session cookies to bypass multi-factor authentication systems.(Citation: Unit 42 Mac Crypto Cookies January 2019)

The tag is: *misp-galaxy:mitre-attack-pattern="Web Session Cookie - T1550.004"*

Credential API Hooking - T1056.004

Adversaries may hook into Windows application programming interface (API) functions and Linux system functions to collect user credentials. Malicious hooking mechanisms may capture API or function calls that include parameters that reveal user authentication credentials.(Citation: Microsoft TrojanSpy:Win32/Ursnif.gen!I Sept 2017) Unlike [Keylogging](https://attack.mitre.org/techniques/T1056/001), this technique focuses specifically on API functions that include parameters that reveal user credentials.

In Windows, hooking involves redirecting calls to these functions and can be implemented via:

- **Hooks procedures**, which intercept and execute designated code in response to events such as messages, keystrokes, and mouse inputs.(Citation: Microsoft Hook Overview)(Citation: Elastic Process Injection July 2017)
- **Import address table (IAT) hooking**, which use modifications to a process's IAT, where pointers to imported API functions are stored.(Citation: Elastic Process Injection July 2017)(Citation: Adlice Software IAT Hooks Oct 2014)(Citation: MWRInfoSecurity Dynamic Hooking 2015)
- **Inline hooking**, which overwrites the first bytes in an API function to redirect code flow.(Citation: Elastic Process Injection July 2017)(Citation: HighTech Bridge Inline Hooking Sept 2011)(Citation: MWRInfoSecurity Dynamic Hooking 2015)

In Linux and macOS, adversaries may hook into system functions via the `LD_PRELOAD` (Linux) or `DYLD_INSERT_LIBRARIES` (macOS) environment variables, which enables loading shared libraries into a program's address space. For example, an adversary may capture credentials by hooking into the `libc read` function leveraged by SSH or SCP.(Citation: Intezer Symbiote 2022)

SSH Authorized Keys - T1098.004

Adversaries may modify the SSH <code>authorized_keys</code> file to maintain persistence on a victim host. Linux distributions, macOS, and ESXi hypervisors commonly use key-based authentication to secure the authentication process of SSH sessions for remote management. The <code>authorized_keys</code> file in SSH specifies the SSH keys that can be used for logging into the user account for which the file is configured. This file is usually found in the user's home directory under <code><user-home>/.ssh/authorized_keys</code> (or, on ESXi, `/etc/ssh/keys-<username>/authorized_keys`).(Citation: SSH Authorized Keys) Users may edit the system's SSH config file to modify the directives `PubkeyAuthentication` and `RSAAuthentication` to the value `yes` to ensure public key and RSA authentication are enabled, as well as modify the directive `PermitRootLogin` to the value `yes` to enable root authentication via SSH.(Citation: Broadcom ESXi SSH) The SSH config file is usually located under <code>/etc/ssh/sshd_config</code>.

Adversaries may modify SSH <code>authorized_keys</code> files directly with scripts or shell commands to add their own adversary-supplied public keys. In cloud environments, adversaries may be able to modify the SSH authorized_keys file of a particular virtual machine via the command line interface or rest API. For example, by using the Google Cloud CLI's "add-metadata" command an adversary may add SSH keys to a user account.(Citation: Google Cloud Add

Metadata)(Citation: Google Cloud Privilege Escalation) Similarly, in Azure, an adversary may update the authorized_keys file of a virtual machine via a PATCH request to the API.(Citation: Azure Update Virtual Machines) This ensures that an adversary possessing the corresponding private key may log in as an existing user via SSH.(Citation: Venafi SSH Key Abuse)(Citation: Cybereason Linux Exim Worm) It may also lead to privilege escalation where the virtual machine or instance has distinct permissions from the requesting user.

Where authorized_keys files are modified via cloud APIs or command line interfaces, an adversary may achieve privilege escalation on the target virtual machine if they add a key to a higher-privileged user.

SSH keys can also be added to accounts on network devices, such as with the `ip ssh pubkey-chain` [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) command.(Citation: cisco_ip_ssh_pubkey_ch_cmd)

The tag is: *misp-galaxy:mitre-attack-pattern="SSH Authorized Keys - T1098.004"*

Terminal Services DLL - T1505.005

Adversaries may abuse components of Terminal Services to enable persistent access to systems. Microsoft Terminal Services, renamed to Remote Desktop Services in some Windows Server OSs as of 2022, enable remote terminal connections to hosts. Terminal Services allows servers to transmit a full, interactive, graphical user interface to clients via RDP.(Citation: Microsoft Remote Desktop Services)

[Windows Service](https://attack.mitre.org/techniques/T1543/003)s that are run as a "generic" process (ex: <code>svchost.exe</code>) load the service's DLL file, the location of which is stored in a Registry entry named <code>ServiceDll</code>.(Citation: Microsoft System Services

Fundamentals) The <code>termsrv.dll</code> file, typically stored in `%SystemRoot%\System32\`, is the default <code>ServiceDll</code> value for Terminal Services in `HKLM\System\CurrentControlSet\services\TermService\Parameters\`.

Adversaries may modify and/or replace the Terminal Services DLL to enable persistent access to victimized hosts.(Citation: James TermServ DLL) Modifications to this DLL could be done to execute arbitrary payloads (while also potentially preserving normal <code>termsrv.dll</code> functionality) as well as to simply enable abusable features of Terminal Services. For example, an adversary may enable features such as concurrent [Remote Desktop Protocol](https://attack.mitre.org/techniques/T1021/001) sessions by either patching the <code>termsrv.dll</code> file or modifying the <code>ServiceDll</code> value to point to a DLL that provides increased RDP functionality.(Citation: Windows OS Hub RDP)(Citation: RDPWrap Github) On a non-server Windows OS this increased functionality may also enable an adversary to avoid Terminal Services prompts that warn/log out users of a system when a new RDP session is created.

Thread Local Storage - T1055.005

Adversaries may inject malicious code into processes via thread local storage (TLS) callbacks in order to evade process-based defenses as well as possibly elevate privileges. TLS callback injection is a method of executing arbitrary code in the address space of a separate live process.

TLS callback injection involves manipulating pointers inside a portable executable (PE) to redirect a process to malicious code before reaching the code's legitimate entry point. TLS callbacks are normally used by the OS to setup and/or cleanup data used by threads. Manipulating TLS callbacks may be performed by allocating and writing to specific offsets within a process' memory space using other [Process Injection](https://attack.mitre.org/techniques/T1055) techniques such as [Process Hollowing](https://attack.mitre.org/techniques/T1055/012).(Citation: FireEye TLS Nov 2017)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via TLS callback injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Thread Local Storage - T1055.005"*

Table 8301. Table References

vSphere Installation Bundles - T1505.006

Adversaries may abuse vSphere Installation Bundles (VIBs) to establish persistent access to ESXi hypervisors. VIBs are collections of files used for software distribution and virtual system management in VMware environments. Since ESXi uses an in-memory filesystem where changes made to most files are stored in RAM rather than in persistent storage, these modifications are lost after a reboot. However, VIBs can be used to create startup tasks, apply custom firewall rules, or deploy binaries that persist across reboots. Typically, administrators use VIBs for updates and system maintenance.

VIBs can be broken down into three components:(Citation: VMware VIBs)

- VIB payload: a `.vgz` archive containing the directories and files to be created and executed on boot when the VIBs are loaded.
- Signature file: verifies the host acceptance level of a VIB, indicating what testing and validation has been done by VMware or its partners before publication of a VIB. By default, ESXi hosts require a minimum acceptance level of PartnerSupported for VIB installation, meaning the VIB is published by a trusted VMware partner. However, privileged users can change the default acceptance level using the `esxcli` command line interface. Additionally, VIBs are able to be installed regardless of acceptance level by using the <code> esxcli software vib install --force</code> command.
- XML descriptor file: a configuration file containing associated VIB metadata, such as the name of the VIB and its dependencies.

Adversaries may leverage malicious VIB packages to maintain persistent access to ESXi hypervisors, allowing system changes to be executed upon each bootup of ESXi – such as using `esxcli` to enable firewall rules for backdoor traffic, creating listeners on hard coded ports, and executing backdoors.(Citation: Google Cloud Threat Intelligence ESXi VIBs 2022) Adversaries may also masquerade their malicious VIB files as PartnerSupported by modifying the XML descriptor file.(Citation: Google Cloud Threat Intelligence ESXi VIBs 2022)

Ptrace System Calls - T1055.008

Adversaries may inject malicious code into processes via ptrace (process trace) system calls in order to evade process-based defenses as well as possibly elevate privileges. Ptrace system call injection is a method of executing arbitrary code in the address space of a separate live process.

Ptrace system call injection involves attaching to and modifying a running process. The ptrace system call enables a debugging process to observe and control another process (and each individual thread), including changing memory and register values.(Citation: PTRACE man) Ptrace system call injection is commonly performed by writing arbitrary code into a running process (ex: <code>malloc</code>) then invoking that memory with <code>PTRACE_SETREGS</code> to set the register containing the next instruction to execute. Ptrace system call injection can also be done with <code>PTRACE_POKETEXT</code>/<code>PTRACE_POKEDATA</code>, which copy data to a specific address in the target processes' memory (ex: the current address of the next instruction). (Citation: PTRACE man)(Citation: Medium Ptrace JUL 2018)

Ptrace system call injection may not be possible targeting processes that are non-child processes and/or have higher-privileges.(Citation: BH Linux Inject)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via ptrace system call injection may also evade detection from security products since the execution is masked under a legitimate process.

Network Security Appliances - T1590.006

Adversaries may gather information about the victim's network security appliances that can be used during targeting. Information about network security appliances may include a variety of details, such as the existence and specifics of deployed firewalls, content filters, and proxies/bastion hosts. Adversaries may also target information about victim network-based intrusion detection

systems (NIDS) or other appliances related to defensive cybersecurity operations.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](https://attack.mitre.org/techniques/T1595) or [Phishing for Information](https://attack.mitre.org/techniques/T1598).(Citation: Nmap Firewalls NIDS) Information about network security appliances may also be exposed to adversaries via online or other accessible data sets (ex: [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594)). Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Develop Capabilities](https://attack.mitre.org/techniques/T1587) or [Obtain Capabilities](https://attack.mitre.org/techniques/T1588)), and/or initial access (ex: [External Remote Services](https://attack.mitre.org/techniques/T1133)).

Network Device CLI - T1059.008

Adversaries may abuse scripting or built-in command line interpreters (CLI) on network devices to execute malicious command and payloads. The CLI is the primary means through which users and administrators interact with the device in order to view system information, modify device operations, or perform diagnostic and administrative functions. CLIs typically contain various permission levels required for different commands.

Scripting interpreters automate tasks and extend functionality beyond the command set included in the network OS. The CLI and scripting interpreter are accessible through a direct console connection, or through remote means, such as telnet or [SSH](https://attack.mitre.org/techniques/T1021/004).

Adversaries can use the network CLI to change how network devices behave and operate. The CLI may be used to manipulate traffic flows to intercept or manipulate data, modify startup configuration parameters to load malicious system software, or to disable security features or logging to avoid detection.(Citation: Cisco Synful Knock Evolution)

Local Email Collection - T1114.001

Adversaries may target user email on local systems to collect sensitive information. Files containing email data can be acquired from a user's local system, such as Outlook storage or cache files.

Outlook stores data locally in offline data files with an extension of .ost. Outlook 2010 and later supports .ost file sizes up to 50GB, while earlier versions of Outlook support up to 20GB.(Citation: Outlook File Sizes) IMAP accounts in Outlook 2013 (and earlier) and POP accounts use Outlook Data Files (.pst) as opposed to .ost, whereas IMAP accounts in Outlook 2016 (and later) use .ost files. Both types of Outlook data files are typically stored in `C:\Users\<username>\Documents\Outlook Files` or `C:\Users\<username>\AppData\Local\Microsoft\Outlook`.(Citation: Microsoft Outlook Files)

Remote Email Collection - T1114.002

Adversaries may target an Exchange server, Office 365, or Google Workspace to collect sensitive information. Adversaries may leverage a user's credentials and interact directly with the Exchange server to acquire information from within a network. Adversaries may also access externally facing Exchange services, Office 365, or Google Workspace to access email using credentials or access tokens. Tools such as [MailSniper](https://attack.mitre.org/software/S0413) can be used to automate searches for specific keywords.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote Email Collection - T1114.002"*

Table 8307. Table References

Links
https://attack.mitre.org/techniques/T1114/002

Compiled HTML File - T1218.001

Adversaries may abuse Compiled HTML files (.chm) to conceal malicious code. CHM files are commonly distributed as part of the Microsoft HTML Help system. CHM files are compressed compilations of various content such as HTML documents, images, and scripting/web related programming languages such VBA, JScript, Java, and ActiveX. (Citation: Microsoft HTML Help May 2018) CHM content is displayed using underlying components of the Internet Explorer browser (Citation: Microsoft HTML Help ActiveX) loaded by the HTML Help executable program (hh.exe). (Citation: Microsoft HTML Help Executable Program)

A custom CHM file containing embedded payloads could be delivered to a victim then triggered by [User Execution](https://attack.mitre.org/techniques/T1204). CHM execution may also bypass application application control on older and/or unpatched systems that do not account for execution of binaries through hh.exe. (Citation: MsitPros CHM Aug 2017) (Citation: Microsoft CVE-2017-8625 Aug 2017)

Email Forwarding Rule - T1114.003

Adversaries may setup email forwarding rules to collect sensitive information. Adversaries may abuse email forwarding rules to monitor the activities of a victim, steal information, and further gain intelligence on the victim or the victim's organization to use as part of further exploits or operations.(Citation: US-CERT TA18-068A 2018) Furthermore, email forwarding rules can allow adversaries to maintain persistent access to victim's emails even after compromised credentials are reset by administrators.(Citation: Pfammatter - Hidden Inbox Rules) Most email clients allow users to create inbox rules for various email functions, including forwarding to a different recipient. These rules may be created through a local email application, a web interface, or by command-line interface. Messages can be forwarded to internal or external recipients, and there are no restrictions limiting the extent of this rule. Administrators may also create forwarding rules for user accounts with the same considerations and outcomes.(Citation: Microsoft Tim McMichael Exchange Mail Forwarding 2)(Citation: Mac Forwarding Rules)

Any user or administrator within the organization (or adversary with valid credentials) can create rules to automatically forward all received messages to another recipient, forward emails to different locations based on the sender, and more. Adversaries may also hide the rule by making use of the Microsoft Messaging API (MAPI) to modify the rule properties, making it hidden and not visible from Outlook, OWA or most Exchange Administration tools.(Citation: Pfammatter - Hidden Inbox Rules)

In some environments, administrators may be able to enable email forwarding rules that operate organization-wide rather than on individual inboxes. For example, Microsoft Exchange supports transport rules that evaluate all mail an organization receives against user-specified conditions, then performs a user-specified action on mail that adheres to those conditions.(Citation: Microsoft Mail Flow Rules 2023) Adversaries that abuse such features may be able to enable forwarding on all

or specific mail an organization receives.

Overwrite Process Arguments - T1036.011

Adversaries may modify a process's in-memory arguments to change its name in order to appear as a legitimate or benign process. On Linux, the operating system stores command-line arguments in the process's stack and passes them to the `main()` function as the `argv` array. The first element, `argv[0]`, typically contains the process name or path - by default, the command used to actually start the process (e.g., `cat /etc/passwd`). By default, the Linux `/proc` filesystem uses this value to represent the process name. The `/proc/<PID>/cmdline` file reflects the contents of this memory, and tools like `ps` use it to display process information. Since arguments are stored in user-space memory at launch, this modification can be performed without elevated privileges.

During runtime, adversaries can erase the memory used by all command-line arguments for a process, overwriting each argument string with null bytes. This removes evidence of how the process was originally launched. They can then write a spoofed string into the memory region previously occupied by `argv[0]` to mimic a benign command, such as `cat resolv.conf`. The new command-line string is reflected in `/proc/<PID>/cmdline` and displayed by tools like `ps`.(Citation: Sandfly BPFDoor 2022)(Citation: Microsoft XorDdos Linux Stealth 2022)

Ptrace System Calls - T1631.001

Adversaries may inject malicious code into processes via ptrace (process trace) system calls in order to evade process-based defenses as well as possibly elevate privileges. Ptrace system call injection is a method of executing arbitrary code in the address space of a separate live process.

Ptrace system call injection involves attaching to and modifying a running process. The ptrace system call enables a debugging process to observe and control another process (and each individual thread), including changing memory and register values.(Citation: PTRACE man) Ptrace system call injection is commonly performed by writing arbitrary code into a running process (e.g., by using `malloc`) then invoking that memory with `PTRACE_SETREGS` to set the register containing the next instruction to execute. Ptrace system call injection can also be done with `PTRACE_POKETEXT` /`PTRACE_POKEDATA`, which copy data to a specific address in the target process's memory (e.g., the current address of the next instruction).(Citation: PTRACE man)(Citation: Medium Ptrace JUL 2018)

Ptrace system call injection may not be possible when targeting processes with high-privileges, and on some systems those that are non-child processes.(Citation: BH Linux Inject)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via ptrace system call injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Ptrace System Calls - T1631.001"*

Office Template Macros - T1137.001

Adversaries may abuse Microsoft Office templates to obtain persistence on a compromised system. Microsoft Office contains templates that are part of common Office applications and are used to customize styles. The base templates within the application are used each time an application starts. (Citation: Microsoft Change Normal Template)

Office Visual Basic for Applications (VBA) macros (Citation: MSDN VBA in Office) can be inserted into the base template and used to execute code when the respective Office application starts in order to obtain persistence. Examples for both Word and Excel have been discovered and published. By default, Word has a Normal.dotm template created that can be modified to include a malicious macro. Excel does not have a template file created by default, but one can be added that will automatically be loaded.(Citation: enigma0x3 normal.dotm)(Citation: Hexacorn Office Template Macros) Shared templates may also be stored and pulled from remote locations.(Citation:

GlobalDotName Jun 2019)

Word Normal.dotm location:
 <code>C:\Users<username>\AppData\Roaming\Microsoft\Templates\Normal.dotm</code>

Excel Personal.xlsb location:
 <code>C:\Users<username>\AppData\Roaming\Microsoft\Excel\XLSTART\PERSONAL.XLSB</code>

Adversaries may also change the location of the base template to point to their own by hijacking the application's search order, e.g. Word 2016 will first look for Normal.dotm under <code>C:\Program Files (x86)\Microsoft Office\root\Office16\</code>, or by modifying the GlobalDotName registry key. By modifying the GlobalDotName registry key an adversary can specify an arbitrary location, file name, and file extension to use for the template that will be loaded on application startup. To abuse GlobalDotName, adversaries may first need to register the template as a trusted document or place it in a trusted location.(Citation: GlobalDotName Jun 2019)

An adversary may need to enable macros to execute unrestricted depending on the system or enterprise security policy on use of macros.

System Language Discovery - T1614.001

Adversaries may attempt to gather information about the system language of a victim in order to infer the geographical location of that host. This information may be used to shape follow-on behaviors, including whether the adversary infects the target and/or attempts specific actions. This decision may be employed by malware developers and operators to reduce their risk of attracting the attention of specific law enforcement agencies or prosecution/scrutiny from other entities.(Citation: Malware System Language Check)

There are various sources of data an adversary could use to infer system language, such as system defaults and keyboard layouts. Specific checks will vary based on the target and/or adversary, but

may involve behaviors such as [Query Registry](https://attack.mitre.org/techniques/T1012) and calls to [Native API](https://attack.mitre.org/techniques/T1106) functions.(Citation: CrowdStrike Ryuk January 2019)

For example, on a Windows system adversaries may attempt to infer the language of a system by querying the registry key <code>HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Nls\Language</code> or parsing the outputs of Windows API functions <code>GetUserDefaultUILanguage</code>, <code>GetSystemDefaultUILanguage</code>, <code>GetKeyboardLayoutList</code> and <code>GetUserDefaultLangID</code>.(Citation: Darkside Ransomware Cybereason)(Citation: Securelist JSWorm)(Citation: SecureList SynAck Doppelgänging May 2018)

On a macOS or Linux system, adversaries may query <code>locale</code> to retrieve the value of the <code>$LANG</code> environment variable.

Transmitted Data Manipulation - T1641.001

Adversaries may alter data en route to storage or other systems in order to manipulate external outcomes or hide activity. By manipulating transmitted data, adversaries may attempt to affect a business process, organizational understanding, or decision making.

Manipulation may be possible over a network connection or between system processes where there is an opportunity to deploy a tool that will intercept and change information. The type of modification and the impact it will have depends on the target transmission mechanism as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system, typically gained through a prolonged information gathering campaign, in order to have the desired impact.

One method to achieve [Transmitted Data Manipulation](https://attack.mitre.org/techniques/T1641/001) is by modifying the contents of the device clipboard. Malicious applications may monitor clipboard activity through the `ClipboardManager.OnPrimaryClipChangedListener` interface on Android to determine when clipboard contents have changed. Listening to clipboard activity, reading clipboard contents, and modifying clipboard contents requires no explicit application permissions and can be performed by applications running in the background. However, this behavior has

changed with the release of Android 10.

Adversaries may use [Transmitted Data Manipulation](https://attack.mitre.org/techniques/T1641/001) to replace text prior to being pasted. For example, replacing a copied Bitcoin wallet address with a wallet address that is under adversarial control.

[Transmitted Data Manipulation](https://attack.mitre.org/techniques/T1641/001) was seen within the Android/Clipper.C trojan. This sample was detected by ESET in an application distributed through the Google Play Store targeting cryptocurrency wallet numbers.(Citation: ESET Clipboard Modification February 2019)

The tag is: *misp-galaxy:mitre-attack-pattern="Transmitted Data Manipulation - T1641.001"*

Dead Drop Resolver - T1481.001

Adversaries may use an existing, legitimate external Web service to host information that points to additional command and control (C2) infrastructure. Adversaries may post content, known as a dead drop resolver, on Web services with embedded (and often obfuscated/encoded) domains or IP addresses. Once infected, victims will reach out to and be redirected by these resolvers.

Popular websites and social media, acting as a mechanism for C2, may give a significant amount of cover. This is due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

Use of a dead drop resolver may also protect back-end C2 infrastructure from discovery through malware binary analysis, or enable operational resiliency (since this infrastructure may be dynamically changed).

Disk Content Wipe - T1561.001

Adversaries may erase the contents of storage devices on specific systems or in large numbers in a network to interrupt availability to system and network resources.

Adversaries may partially or completely overwrite the contents of a storage device rendering the data irrecoverable through the storage interface.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware)(Citation: DOJ Lazarus Sony 2018) Instead of wiping specific disk structures or files, adversaries with destructive intent may wipe arbitrary portions of disk content. To wipe disk content, adversaries may acquire direct access to the hard drive in order to overwrite arbitrarily sized portions of disk with random data.(Citation: Novetta Blockbuster Destructive Malware) Adversaries have also been observed leveraging third-party drivers like [RawDisk](https://attack.mitre.org/software/S0364) to directly access disk content.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware) This behavior is distinct from [Data Destruction](https://attack.mitre.org/techniques/T1485) because sections of the disk are erased instead of individual files.

To maximize impact on the target organization in operations where network-wide availability interruption is the goal, malware used for wiping disk content may have worm-like features to propagate across a network by leveraging additional techniques like [Valid Accounts](https://attack.mitre.org/techniques/T1078), [OS Credential Dumping](https://attack.mitre.org/techniques/T1003), and [SMB/Windows Admin Shares](https://attack.mitre.org/techniques/T1021/002).(Citation: Novetta Blockbuster Destructive Malware)

The tag is: *misp-galaxy:mitre-attack-pattern="Disk Content Wipe - T1561.001"*

Security Software Discovery - T1518.001

Adversaries may attempt to get a listing of security software, configurations, defensive tools, and sensors that are installed on a system or in a cloud environment. This may include things such as cloud monitoring agents and anti-virus. Adversaries may use the information from [Security Software Discovery](https://attack.mitre.org/techniques/T1518/001) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Example commands that can be used to obtain security software information are [netsh](https://attack.mitre.org/software/S0108), <code>reg query</code> with [Reg](https://attack.mitre.org/software/S0075), <code>dir</code> with [cmd](https://attack.mitre.org/software/S0106), and [Tasklist](https://attack.mitre.org/software/S0057), but other indicators of discovery behavior may be more specific to the type of software or security system the adversary is looking for. It is becoming more common to see macOS malware perform checks for LittleSnitch and KnockKnock software.

Adversaries may also utilize the [Cloud API](https://attack.mitre.org/techniques/T1059/009) to discover cloud-native security software installed on compute infrastructure, such as the AWS CloudWatch agent, Azure VM Agent, and Google Cloud Monitor agent. These agents may collect metrics and logs from the VM, which may be centrally aggregated in a cloud-based monitoring platform.

Determine Physical Locations - T1591.001

Adversaries may gather the victim's physical location(s) that can be used during targeting. Information about physical locations of a target organization may include a variety of details, including where key resources and infrastructure are housed. Physical locations may also indicate what legal jurisdiction and/or authorities the victim operates within.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](https://attack.mitre.org/techniques/T1598). Physical locations of a target organization may also be exposed to adversaries via online or other accessible data sets (ex: [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594) or [Social Media](https://attack.mitre.org/techniques/T1593/001)).(Citation: ThreatPost Broadvoice Leak)(Citation: SEC EDGAR Search) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](https://attack.mitre.org/techniques/T1598) or [Search Open Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Develop Capabilities](https://attack.mitre.org/techniques/T1587) or

[Obtain Capabilities](https://attack.mitre.org/techniques/T1588)), and/or initial access (ex: [Phishing](https://attack.mitre.org/techniques/T1566) or [Hardware Additions](https://attack.mitre.org/techniques/T1200)).

LNK Icon Smuggling - T1027.012

Adversaries may smuggle commands to download malicious payloads past content filters by hiding them within otherwise seemingly benign windows shortcut files. Windows shortcut files (.LNK) include many metadata fields, including an icon location field (also known as the `IconEnvironmentDataBlock`) designed to specify the path to an icon file that is to be displayed for the LNK file within a host directory.

Adversaries may abuse this LNK metadata to download malicious payloads. For example, adversaries have been observed using LNK files as phishing payloads to deliver malware. Once invoked (e.g., [Malicious File](https://attack.mitre.org/techniques/T1204/002)), payloads referenced via external URLs within the LNK icon location field may be downloaded. These files may also then be invoked by [Command and Scripting Interpreter](System Binary Proxy Execution (https://attack.mitre.org/techniques/T1218) arguments within the target path field of the LNK.(Citation: Unprotect Shortcut)(Citation: Booby Trap Shortcut 2017)

LNK Icon Smuggling may also be utilized post compromise, such as malicious scripts executing an

LNK on an infected host to download additional malicious payloads.

The tag is: *misp-galaxy:mitre-attack-pattern="LNK Icon Smuggling - T1027.012"*

GUI Input Capture - T1417.002

Adversaries may mimic common operating system GUI components to prompt users for sensitive information with a seemingly legitimate prompt. The operating system and installed applications often have legitimate needs to prompt the user for sensitive information such as account credentials, bank account information, or Personally Identifiable Information (PII). Compared to traditional PCs, the constrained display size of mobile devices may impair the ability to provide users with contextual information, making users more susceptible to this technique's use.(Citation: Felt-PhishingOnMobileDevices)

There are several approaches adversaries may use to mimic this functionality. Adversaries may impersonate the identity of a legitimate application (e.g. use the same application name and/or icon) and, when installed on the device, may prompt the user for sensitive information.(Citation: eset-finance) Adversaries may also send fake device notifications to the user that may trigger the display of an input prompt when clicked.(Citation: Group IB Gustuff Mar 2019)

Additionally, adversaries may display a prompt on top of a running, legitimate application to trick users into entering sensitive information into a malicious application rather than the legitimate application. Typically, adversaries need to know when the targeted application and the individual activity within the targeted application is running in the foreground to display the prompt at the proper time. Adversaries can abuse Android's accessibility features to determine which application is currently in the foreground.(Citation: ThreatFabric Cerberus) Two known approaches to displaying a prompt include:

- Adversaries start a new activity on top of a running legitimate application.(Citation: Felt-PhishingOnMobileDevices)(Citation: Hassell-ExploitingAndroid) Android 10 places new restrictions on the ability for an application to start a new activity on top of another application, which may make it more difficult for adversaries to utilize this technique.(Citation: Android Background)
- Adversaries create an application overlay window on top of a running legitimate application.

Applications must hold the `SYSTEM_ALERT_WINDOW` permission to create overlay windows. This permission is handled differently than typical Android permissions and, at least under certain conditions, is automatically granted to applications installed from the Google Play Store.(Citation: Cloak and Dagger)(Citation: NowSecure Android Overlay)(Citation: Skycure-Accessibility) The `SYSTEM_ALERT_WINDOW` permission and its associated ability to create application overlay windows are expected to be deprecated in a future release of Android in favor of a new API.(Citation: XDA Bubbles)

Credentials In Files - T1552.001

Adversaries may search local file systems and remote file shares for files containing insecurely stored credentials. These can be files created by users to store their own credentials, shared credential stores for a group of individuals, configuration files containing passwords for a system or service, or source code/binary files containing embedded passwords.

It is possible to extract passwords from backups or saved virtual machines through [OS Credential Dumping](https://attack.mitre.org/techniques/T1003).(Citation: CG 2014) Passwords may also be obtained from Group Policy Preferences stored on the Windows Domain Controller.(Citation: SRD GPP)

In cloud and/or containerized environments, authenticated user and service account credentials are often stored in local configuration and credential files.(Citation: Unit 42 Hildegard Malware) They may also be found as parameters to deployment commands in container logs.(Citation: Unit 42

Unsecured Docker Daemons) In some cases, these files can be copied and reused on another machine or the contents can be read and then used to authenticate without needing to copy any files.(Citation: Specter Ops - Cloud Credential Storage)

Disk Structure Wipe - T1561.002

Adversaries may corrupt or wipe the disk data structures on a hard drive necessary to boot a system; targeting specific critical systems or in large numbers in a network to interrupt availability to system and network resources.

Adversaries may attempt to render the system unable to boot by overwriting critical data located in structures such as the master boot record (MBR) or partition table.(Citation: Symantec Shamoon 2012)(Citation: FireEye Shamoon Nov 2016)(Citation: Palo Alto Shamoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)(Citation: Unit 42 Shamoon3 2018) The data contained in disk structures may include the initial executable code for loading an operating system or the location of the file system partitions on disk. If this information is not present, the computer will not be able to load an operating system during the boot process, leaving the computer unavailable. [Disk Structure Wipe](https://attack.mitre.org/techniques/T1561/002) may be performed in isolation, or along with [Disk Content Wipe](https://attack.mitre.org/techniques/T1561/001) if all sectors of a disk are wiped.

On a network devices, adversaries may reformat the file system using [Network Device CLI](https://attack.mitre.org/techniques/T1059/008) commands such as `format`.(Citation: format_cmd_cisco)

To maximize impact on the target organization, malware designed for destroying disk structures may have worm-like features to propagate across a network by leveraging other techniques like [Valid Accounts](https://attack.mitre.org/techniques/T1078), [OS Credential Dumping](https://attack.mitre.org/techniques/T1003), and [SMB/Windows Admin Shares](https://attack.mitre.org/techniques/T1021/002).(Citation: Symantec Shamoon 2012)(Citation: FireEye Shamoon Nov 2016)(Citation: Palo Alto Shamoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)

Backup Software Discovery - T1518.002

Adversaries may attempt to get a listing of backup software or configurations that are installed on a system. Adversaries may use this information to shape follow-on behaviors, such as [Data Destruction](https://attack.mitre.org/techniques/T1485), [Inhibit System Recovery](https://attack.mitre.org/techniques/T1490), or [Data Encrypted for Impact](https://attack.mitre.org/techniques/T1486).

Commands that can be used to obtain security software information are [netsh](https://attack.mitre.org/software/S0108), `reg query` with [Reg](https://attack.mitre.org/software/S0075), `dir` with [cmd](https://attack.mitre.org/software/S0106), and [Tasklist](https://attack.mitre.org/software/S0057), but other indicators of discovery behavior may be more specific to the type of software or security system the adversary is looking for, such as Veeam, Acronis, Dropbox, or Paragon.(Citation: Symantec Play Ransomware 2023)

Device Administrator Permissions - T1626.001

Adversaries may abuse Android's device administration API to obtain a higher degree of control over the device. By abusing the API, adversaries can perform several nefarious actions, such as resetting the device's password for [Endpoint Denial of Service](https://attack.mitre.org/techniques/T1642), factory resetting the device for [File Deletion](https://attack.mitre.org/techniques/T1630/002) and to delete any traces of the malware, disabling all the device's cameras, or to make it more

difficult to uninstall the app.

Device administrators must be approved by the user at runtime, with a system popup showing which actions have been requested by the app. In conjunction with other techniques, such as [Input Injection](https://attack.mitre.org/techniques/T1516), an app can programmatically grant itself administrator permissions without any user input.

The tag is: *misp-galaxy:mitre-attack-pattern="Device Administrator Permissions - T1626.001"*

Table 8328. Table References

Junk Code Insertion - T1027.016

Adversaries may use junk code / dead code to obfuscate a malware's functionality. Junk code is code that either does not execute, or if it does execute, does not change the functionality of the code. Junk code makes analysis more difficult and time-consuming, as the analyst steps through non-functional code instead of analyzing the main code. It also may hinder detections that rely on static code analysis due to the use of benign functionality, especially when combined with [Compression](https://attack.mitre.org/techniques/T1027/015) or [Software Packing](https://attack.mitre.org/techniques/T1027/002).(Citation: ReasonLabs)(Citation: ReasonLabs Cyberpedia Junk Code)

No-Operation (NOP) instructions are an example of dead code commonly used in x86 assembly language. They are commonly used as the 0x90 opcode. When NOPs are added to malware, the disassembler may show the NOP instructions, leading to the analyst needing to step through them.(Citation: ReasonLabs)

The use of junk / dead code insertion is distinct from [Binary Padding](https://attack.mitre.org/techniques/T1027/001) because the purpose is to obfuscate the functionality of the code, rather than simply to change the malware's signature.

The tag is: *misp-galaxy:mitre-attack-pattern="Junk Code Insertion - T1027.016"*

Suppress Application Icon - T1628.001

A malicious application could suppress its icon from being displayed to the user in the application launcher. This hides the fact that it is installed, and can make it more difficult for the user to

uninstall the application. Hiding the application's icon programmatically does not require any special permissions.

This behavior has been seen in the BankBot/Spy Banker family of malware.(Citation: android-trojan-steals-paypal-2fa)(Citation: sunny-stolen-credentials)(Citation: bankbot-spybanker)

Beginning in Android 10, changes were introduced to inhibit malicious applications' ability to hide their icon. If an app is a system app, requests no permissions, or does not have a launcher activity, the application's icon will be fully hidden. Further, if the device is fully managed or the application is in a work profile, the icon will be fully hidden. Otherwise, a synthesized activity is shown, which is a launcher icon that represents the app's details page in the system settings. If the user clicks the synthesized activity in the launcher, they are taken to the application's details page in the system settings.(Citation: Android 10 Limitations to Hiding App Icons)(Citation: LauncherApps getActivityList)

Prevent Application Removal - T1629.001

Adversaries may abuse the Android device administration API to prevent the user from uninstalling a target application. In earlier versions of Android, device administrator applications needed their administration capabilities explicitly deactivated by the user before the application could be uninstalled. This was later updated so the user could deactivate and uninstall the administrator application in one step.

Adversaries may also abuse the device accessibility APIs to prevent removal. This set of APIs allows the application to perform certain actions on behalf of the user and programmatically determine what is being shown on the screen. The malicious application could monitor the device screen for certain modals (e.g., the confirmation modal to uninstall an application) and inject screen input or a back button tap to close the modal. For example, Android's `performGlobalAction(int)` API could be utilized to prevent the user from removing the malicious application from the device after installation. If the user wants to uninstall the malicious application, two cases may occur, both preventing the user from removing the application.

- Case 1: If the integer argument passed to the API call is `2` or `GLOBAL_ACTION_HOME`, the malicious application may direct the user to the home screen from settings screen

- Case 2: If the integer argument passed to the API call is `1` or `GLOBAL_ACTION_BACK`, the malicious application may emulate the back press event

The tag is: *misp-galaxy:mitre-attack-pattern="Prevent Application Removal - T1629.001"*

Parent PID Spoofing - T1134.004

Adversaries may spoof the parent process identifier (PPID) of a new process to evade process-monitoring defenses or to elevate privileges. New processes are typically spawned directly from their parent, or calling, process unless explicitly specified. One way of explicitly assigning the PPID of a new process is via the <code>CreateProcess</code> API call, which supports a parameter that defines the PPID to use.(Citation: DidierStevens SelectMyParent Nov 2009) This functionality is used by Windows features such as User Account Control (UAC) to correctly set the PPID after a requested elevated process is spawned by SYSTEM (typically via <code>svchost.exe</code> or <code>consent.exe</code>) rather than the current user context.(Citation: Microsoft UAC Nov 2018)

Adversaries may abuse these mechanisms to evade defenses, such as those blocking processes spawning directly from Office documents, and analysis targeting unusual/potentially malicious parent-child process relationships, such as spoofing the PPID of [PowerShell](Rundll32 (https://attack.mitre.org/techniques/T1218/011) to be <code>explorer.exe</code> rather than an Office document delivered as part of [Spearphishing Attachment](https://attack.mitre.org/techniques/T1566/001).(Citation: CounterCept PPID Spoofing Dec 2018) This spoofing could be executed via [Visual Basic](https://attack.mitre.org/techniques/T1059/005) within a malicious Office document or any code that can perform [Native API](https://attack.mitre.org/techniques/T1106).(Citation: CTD PPID Spoofing Macro Mar 2019)(Citation: CounterCept PPID Spoofing Dec 2018)

Explicitly assigning the PPID may also enable elevated privileges given appropriate access rights to the parent process. For example, an adversary in a privileged user context (i.e. administrator) may spawn a new process and assign the parent as a process running as SYSTEM (such as <code>lsass.exe</code>), causing the new process to be elevated via the inherited access token.(Citation: XPNSec PPID Nov 2017)

Outlook Home Page - T1137.004

Adversaries may abuse Microsoft Outlook's Home Page feature to obtain persistence on a compromised system. Outlook Home Page is a legacy feature used to customize the presentation of Outlook folders. This feature allows for an internal or external URL to be loaded and presented whenever a folder is opened. A malicious HTML page can be crafted that will execute code when loaded by Outlook Home Page.(Citation: SensePost Outlook Home Page)

Once malicious home pages have been added to the user's mailbox, they will be loaded when Outlook is started. Malicious Home Pages will execute when the right Outlook folder is loaded/reloaded.(Citation: SensePost Outlook Home Page)

The tag is: *misp-galaxy:mitre-attack-pattern="Outlook Home Page - T1137.004"*

Identify Business Tempo - T1591.003

Adversaries may gather information about the victim's business tempo that can be used during targeting. Information about an organization's business tempo may include a variety of details, including operational hours/days of the week. This information may also reveal times/dates of purchases and shipments of the victim's hardware and software resources.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](https://attack.mitre.org/techniques/T1598). Information about business tempo may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](https://attack.mitre.org/techniques/T1593/001) or [Search Victim-Owned Websites](https://attack.mitre.org/techniques/T1594)).(Citation: ThreatPost Broadvoice Leak) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](https://attack.mitre.org/techniques/T1598) or [Search Open

Websites/Domains](https://attack.mitre.org/techniques/T1593)), establishing operational resources (ex: [Establish Accounts](https://attack.mitre.org/techniques/T1585) or [Compromise Accounts](https://attack.mitre.org/techniques/T1586)), and/or initial access (ex: [Supply Chain Compromise](https://attack.mitre.org/techniques/T1195) or [Trusted Relationship](https://attack.mitre.org/techniques/T1199))

The tag is: *misp-galaxy:mitre-attack-pattern="Identify Business Tempo - T1591.003"*

Domain Generation Algorithms - T1637.001

Adversaries may use [Domain Generation Algorithms](https://attack.mitre.org/techniques/T1637/001) (DGAs) to procedurally generate domain names for uses such as command and control communication or malicious application distribution.(Citation: securelist rotexy 2018)

DGAs increase the difficulty for defenders to block, track, or take over the command and control channel, as there could potentially be thousands of domains that malware can check for instructions.

The tag is: *misp-galaxy:mitre-attack-pattern="Domain Generation Algorithms - T1637.001"*

Table 8335. Table References

Group Policy Modification - T1484.001

Adversaries may modify Group Policy Objects (GPOs) to subvert the intended discretionary access controls for a domain, usually with the intention of escalating privileges on the domain. Group policy allows for centralized management of user and computer settings in Active Directory (AD). GPOs are containers for group policy settings made up of files stored within a predictable network path `\<DOMAIN>\SYSVOL\<DOMAIN>\Policies\`.(Citation: TechNet Group Policy Basics)(Citation: ADSecurity GPO Persistence 2016)

Like other objects in AD, GPOs have access controls associated with them. By default all user accounts in the domain have permission to read GPOs. It is possible to delegate GPO access control permissions, e.g. write access, to specific users or groups in the domain.

Malicious GPO modifications can be used to implement many other malicious behaviors such as [Scheduled Task/Job](https://attack.mitre.org/techniques/T1053), [Disable or Modify

Tools](https://attack.mitre.org/techniques/T1562/001), [Ingress Tool Transfer](https://attack.mitre.org/techniques/T1105), [Create Account](https://attack.mitre.org/techniques/T1136), [Service Execution](https://attack.mitre.org/techniques/T1569/002), and more.(Citation: ADSecurity GPO Persistence 2016)(Citation: Wald0 Guide to GPOs)(Citation: Harmj0y Abusing GPO Permissions)(Citation: Mandiant M Trends 2016)(Citation: Microsoft Hacking Team Breach) Since GPOs can control so many user and machine settings in the AD environment, there are a great number of potential attacks that can stem from this GPO abuse.(Citation: Wald0 Guide to GPOs)

For example, publicly available scripts such as <code>New-GPOImmediateTask</code> can be leveraged to automate the creation of a malicious [Scheduled Task/Job](https://attack.mitre.org/techniques/T1053) by modifying GPO settings, in this case modifying <code><GPO_PATH>\Machine\Preferences\ScheduledTasks\ScheduledTasks.xml</code>.(Citation: Wald0 Guide to GPOs)(Citation: Harmj0y Abusing GPO Permissions) In some cases an adversary might modify specific user rights like SeEnableDelegationPrivilege, set in <code><GPO_PATH>\MACHINE\Microsoft\Windows NT\SecEdit\GptTmpl.inf</code>, to achieve a subtle AD backdoor with complete control of the domain because the user account under the adversary's control would then be able to modify GPOs.(Citation: Harmj0y SeEnableDelegationPrivilege Right)

Process Argument Spoofing - T1564.010

Adversaries may attempt to hide process command-line arguments by overwriting process memory. Process command-line arguments are stored in the process environment block (PEB), a data structure used by Windows to store various information about/used by a process. The PEB includes the process command-line arguments that are referenced when executing the process. When a process is created, defensive tools/sensors that monitor process creations may retrieve the process arguments from the PEB.(Citation: Microsoft PEB 2021)(Citation: Xpn Argue Like Cobalt

2019)

Adversaries may manipulate a process PEB to evade defenses. For example, [Process Hollowing](https://attack.mitre.org/techniques/T1055/012) can be abused to spawn a process in a suspended state with benign arguments. After the process is spawned and the PEB is initialized (and process information is potentially logged by tools/sensors), adversaries may override the PEB to modify the command-line arguments (ex: using the [Native API](https://attack.mitre.org/techniques/T1106) <code>WriteProcessMemory()</code> function) then resume process execution with malicious arguments.(Citation: Cobalt Strike Arguments 2019)(Citation: Xpn Argue Like Cobalt 2019)(Citation: Nviso Spoof Command Line 2020)

Adversaries may also execute a process with malicious command-line arguments then patch the memory with benign arguments that may bypass subsequent process memory analysis.(Citation: FireEye FiveHands April 2021)

This behavior may also be combined with other tricks (such as [Parent PID Spoofing](https://attack.mitre.org/techniques/T1134/004)) to manipulate or further evade process-based detections.

Setuid and Setgid - T1548.001

An adversary may abuse configurations where an application has the setuid or setgid bits set in order to get code running in a different (and possibly more privileged) user's context. On Linux or macOS, when the setuid or setgid bits are set for an application binary, the application will run with the privileges of the owning user or group respectively.(Citation: setuid man page) Normally an application is run in the current user's context, regardless of which user or group owns the application. However, there are instances where programs need to be executed in an elevated context to function properly, but the user running them may not have the specific required privileges.

Instead of creating an entry in the sudoers file, which must be done by root, any user can specify

the setuid or setgid flag to be set for their own applications (i.e. [Linux and Mac File and Directory Permissions Modification](https://attack.mitre.org/techniques/T1222/002)). The <code>chmod</code> command can set these bits with bitmasking, <code>chmod 4777 [file]</code> or via shorthand naming, <code>chmod u+s [file]</code>. This will enable the setuid bit. To enable the setgid bit, <code>chmod 2775</code> and <code>chmod g+s</code> can be used.

Adversaries can use this mechanism on their own malware to make sure they're able to execute in elevated contexts in the future.(Citation: OSX Keydnap malware) This abuse is often part of a "shell escape" or other actions to bypass an execution environment with restricted permissions.

Alternatively, adversaries may choose to find and target vulnerable binaries with the setuid or setgid bits already enabled (i.e. [File and Directory Discovery](https://attack.mitre.org/techniques/T1083)). The setuid and setguid bits are indicated with an "s" instead of an "x" when viewing a file's attributes via <code>ls -l</code>. The <code>find</code> command can also be used to search for such files. For example, <code>find / -perm +4000 2>/dev/null</code> can be used to find files with setuid set and <code>find / -perm +2000 2>/dev/null</code> may be used for setgid. Binaries that have these bits set may then be abused by adversaries.(Citation: GTFOBins Suid)

Direct Network Flood - T1498.001

Adversaries may attempt to cause a denial of service (DoS) by directly sending a high-volume of network traffic to a target. This DoS attack may also reduce the availability and functionality of the targeted system(s) and network. [Direct Network Flood](https://attack.mitre.org/techniques/T1498/001)s are when one or more systems are used to send a high-volume of network packets towards the targeted service's network. Almost any network protocol may be used for flooding. Stateless protocols such as UDP or ICMP are commonly used but stateful protocols such as TCP can be used as well.

Botnets are commonly used to conduct network flooding attacks against networks and services. Large botnets can generate a significant amount of traffic from systems spread across the global Internet. Adversaries may have the resources to build out and control their own botnet infrastructure or may rent time on an existing botnet to conduct an attack. In some of the worst cases for distributed DoS (DDoS), so many systems are used to generate the flood that each one only needs to send out a small amount of traffic to produce enough volume to saturate the target network. In such circumstances, distinguishing DDoS traffic from legitimate clients becomes exceedingly difficult. Botnets have been used in some of the most high-profile DDoS flooding attacks, such as the 2012 series of incidents that targeted major US banks.(Citation: USNYAG

IranianBotnet March 2016)

OS Exhaustion Flood - T1499.001

Adversaries may launch a denial of service (DoS) attack targeting an endpoint's operating system (OS). A system's OS is responsible for managing the finite resources as well as preventing the entire system from being overwhelmed by excessive demands on its capacity. These attacks do not need to exhaust the actual resources on a system; the attacks may simply exhaust the limits and available resources that an OS self-imposes.

Different ways to achieve this exist, including TCP state-exhaustion attacks such as SYN floods and ACK floods.(Citation: Arbor AnnualDoSreport Jan 2018) With SYN floods, excessive amounts of SYN packets are sent, but the 3-way TCP handshake is never completed. Because each OS has a maximum number of concurrent TCP connections that it will allow, this can quickly exhaust the ability of the system to receive new requests for TCP connections, thus preventing access to any TCP service provided by the server.(Citation: Cloudflare SynFlood)

ACK floods leverage the stateful nature of the TCP protocol. A flood of ACK packets are sent to the target. This forces the OS to search its state table for a related TCP connection that has already been established. Because the ACK packets are for connections that do not exist, the OS will have to search the entire state table to confirm that no match exists. When it is necessary to do this for a large flood of packets, the computational requirements can cause the server to become sluggish and/or unresponsive, due to the work it must do to eliminate the rogue ACK packets. This greatly reduces the resources available for providing the targeted service.(Citation: Corero SYN-ACKflood)

Domain Controller Authentication - T1556.001

Adversaries may patch the authentication process on a domain controller to bypass the typical authentication mechanisms and enable access to accounts.

Malware may be used to inject false credentials into the authentication process on a domain controller with the intent of creating a backdoor used to access any user's account and/or credentials (ex: [Skeleton Key](https://attack.mitre.org/software/S0007)). Skeleton key works through a patch on an enterprise domain controller authentication process (LSASS) with credentials that adversaries may use to bypass the standard authentication system. Once patched, an adversary can use the injected password to successfully authenticate as any domain user account (until the the skeleton key is erased from memory by a reboot of the domain controller). Authenticated access may enable unfettered access to hosts and/or resources within single-factor authentication environments.(Citation: Dell Skeleton)

Stored Data Manipulation - T1565.001

Adversaries may insert, delete, or manipulate data at rest in order to influence external outcomes or hide activity, thus threatening the integrity of the data.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating stored data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Stored data could include a variety of file formats, such as Office files, databases, stored emails, and custom file formats. The type of modification and the impact it will have depends on the type of data as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

Social Media Accounts - T1585.001

Adversaries may create and cultivate social media accounts that can be used during targeting. Adversaries can create social media accounts that can be used to build a persona to further operations. Persona development consists of the development of public information, presence, history and appropriate affiliations.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage)

For operations incorporating social engineering, the utilization of a persona on social media may be important. These personas may be fictitious or impersonate real people. The persona may exist on a single social media site or across multiple sites (ex: Facebook, LinkedIn, Twitter, etc.). Establishing a persona on social media may require development of additional documentation to make them seem real. This could include filling out profile information, developing social networks, or incorporating photos.

Once a persona has been developed an adversary can use it to create connections to targets of interest. These connections may be direct or may include trying to connect through others.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage) These accounts may be leveraged during other phases of the adversary lifecycle, such as during Initial Access (ex: [Spearphishing via Service](https://attack.mitre.org/techniques/T1566/003)).

Scanning IP Blocks - T1595.001

Adversaries may scan victim IP blocks to gather information that can be used during targeting. Public IP addresses may be allocated to organizations by block, or a range of sequential addresses.

Adversaries may scan IP blocks in order to [Gather Victim Network Information](https://attack.mitre.org/techniques/T1590), such as which IP addresses are actively in use as well as more detailed information about hosts assigned these addresses. Scans may range from simple pings (ICMP requests and responses) to more nuanced scans that may reveal host software/versions via server banners or other network artifacts.(Citation: Botnet Scan) Information from these scans may reveal opportunities for other forms of reconnaissance (ex: [Search Open

Websites/Domains](https://attack.mitre.org/techniques/T1593) or [Search Open Technical Databases](https://attack.mitre.org/techniques/T1596)), establishing operational resources (ex: [Develop Capabilities](https://attack.mitre.org/techniques/T1587) or [Obtain Capabilities](https://attack.mitre.org/techniques/T1588)), and/or initial access (ex: [External Remote Services](https://attack.mitre.org/techniques/T1133)).

Component Object Model - T1559.001

Adversaries may use the Windows Component Object Model (COM) for local code execution. COM is an inter-process communication (IPC) component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces.(Citation: Fireeye Hunting COM June 2019) Through COM, a client object can call methods of server objects, which are typically binary Dynamic Link Libraries (DLL) or executables (EXE).(Citation: Microsoft COM) Remote COM execution is facilitated by [Remote Services](https://attack.mitre.org/techniques/T1021) such as [Distributed Component Object Model](https://attack.mitre.org/techniques/T1021/003) (DCOM).(Citation: Fireeye Hunting COM June 2019)

Various COM interfaces are exposed that can be abused to invoke arbitrary execution via a variety of programming languages such as C, C++, Java, and [Visual Basic](https://attack.mitre.org/techniques/T1059/005).(Citation: Microsoft COM) Specific COM objects also exist to directly perform functions beyond code execution, such as creating a [Scheduled Task/Job](https://attack.mitre.org/techniques/T1053), fileless download/execution, and other adversary behaviors related to privilege escalation and persistence.(Citation: Fireeye Hunting COM June 2019)(Citation: ProjectZero File Write EoP Apr 2018)

Social Media Accounts - T1586.001

Adversaries may compromise social media accounts that can be used during targeting. For operations incorporating social engineering, the utilization of an online persona may be important. Rather than creating and cultivating social media profiles (i.e. [Social Media Accounts](https://attack.mitre.org/techniques/T1585/001)), adversaries may compromise existing social media accounts. Utilizing an existing persona may engender a level of trust in a potential victim if they have a relationship, or knowledge of, the compromised persona.

A variety of methods exist for compromising social media accounts, such as gathering credentials via [Phishing for Information](https://attack.mitre.org/techniques/T1598), purchasing credentials from third-party sites, or by brute forcing credentials (ex: password reuse from breach credential dumps).(Citation: AnonHBGary) Prior to compromising social media accounts, adversaries may conduct Reconnaissance to inform decisions about which accounts to compromise to further their operation.

Personas may exist on a single site or across multiple sites (ex: Facebook, LinkedIn, Twitter, etc.). Compromised social media accounts may require additional development, this could include filling out or modifying profile information, further developing social networks, or incorporating photos.

Adversaries can use a compromised social media profile to create new, or hijack existing, connections to targets of interest. These connections may be direct or may include trying to connect through others.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage) Compromised profiles may be leveraged during other phases of the adversary lifecycle, such as during Initial Access (ex: [Spearphishing via Service](https://attack.mitre.org/techniques/T1566/003)).

Fast Flux DNS - T1568.001

Adversaries may use Fast Flux DNS to hide a command and control channel behind an array of rapidly changing IP addresses linked to a single domain resolution. This technique uses a fully qualified domain name, with multiple IP addresses assigned to it which are swapped with high frequency, using a combination of round robin IP addressing and short Time-To-Live (TTL) for a DNS resource record.(Citation: MehtaFastFluxPt1)(Citation: MehtaFastFluxPt2)(Citation: Fast Flux - Welivesecurity)

The simplest, "single-flux" method, involves registering and de-registering an addresses as part of the DNS A (address) record list for a single DNS name. These registrations have a five-minute average lifespan, resulting in a constant shuffle of IP address resolution.(Citation: Fast Flux - Welivesecurity)
